photon backgrounds

cosmic magnetic fields: extragalactic

Miniati, MNRAS 337 (2002) 199

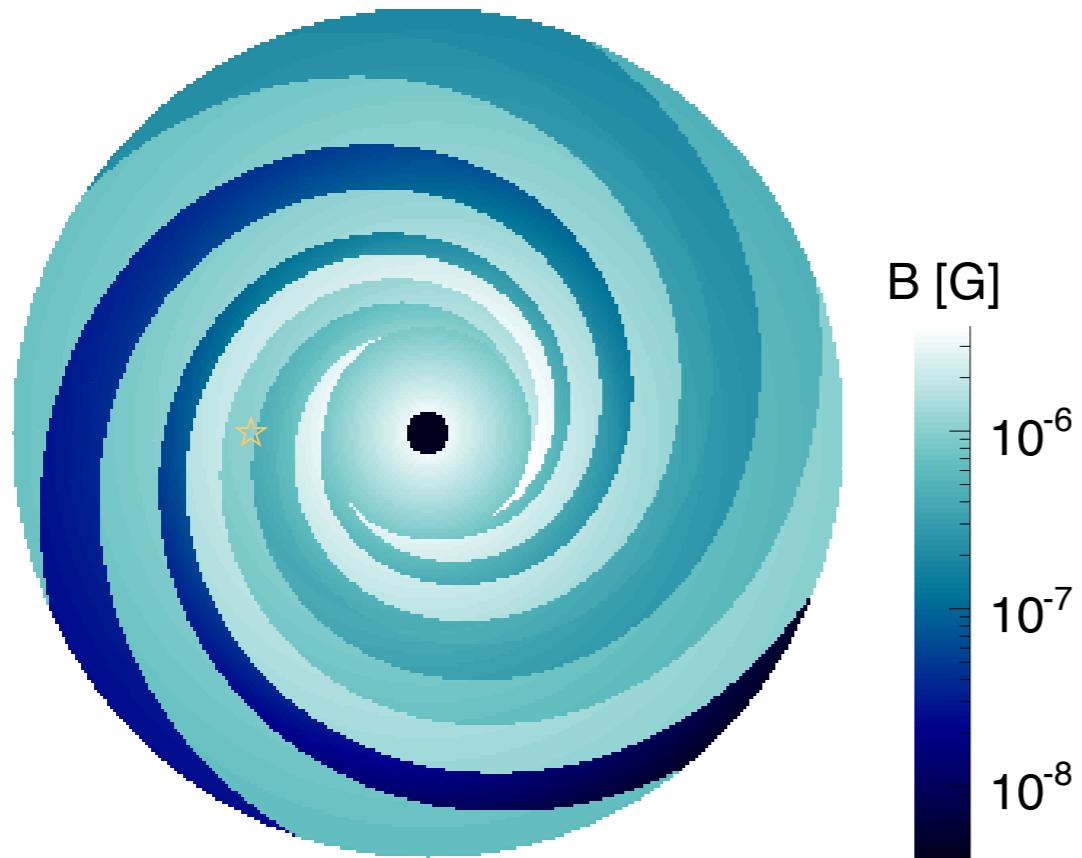

Dolag et al. JCAP 01 (2005) 09

Das et al. ApJ 682 (2008) 29

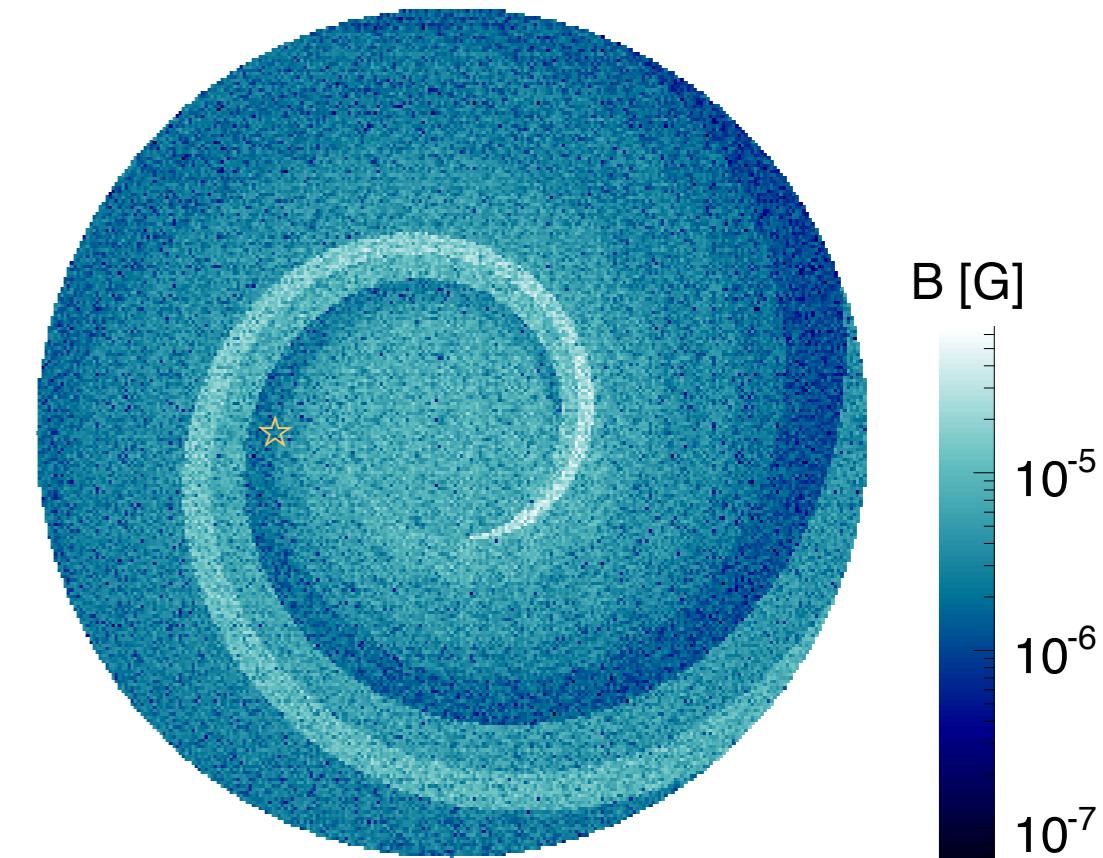

Donnert et al. MNRAS 392 (2009) 1008

cosmic magnetic fields: galactic

Jansson & Farrar model - regular component

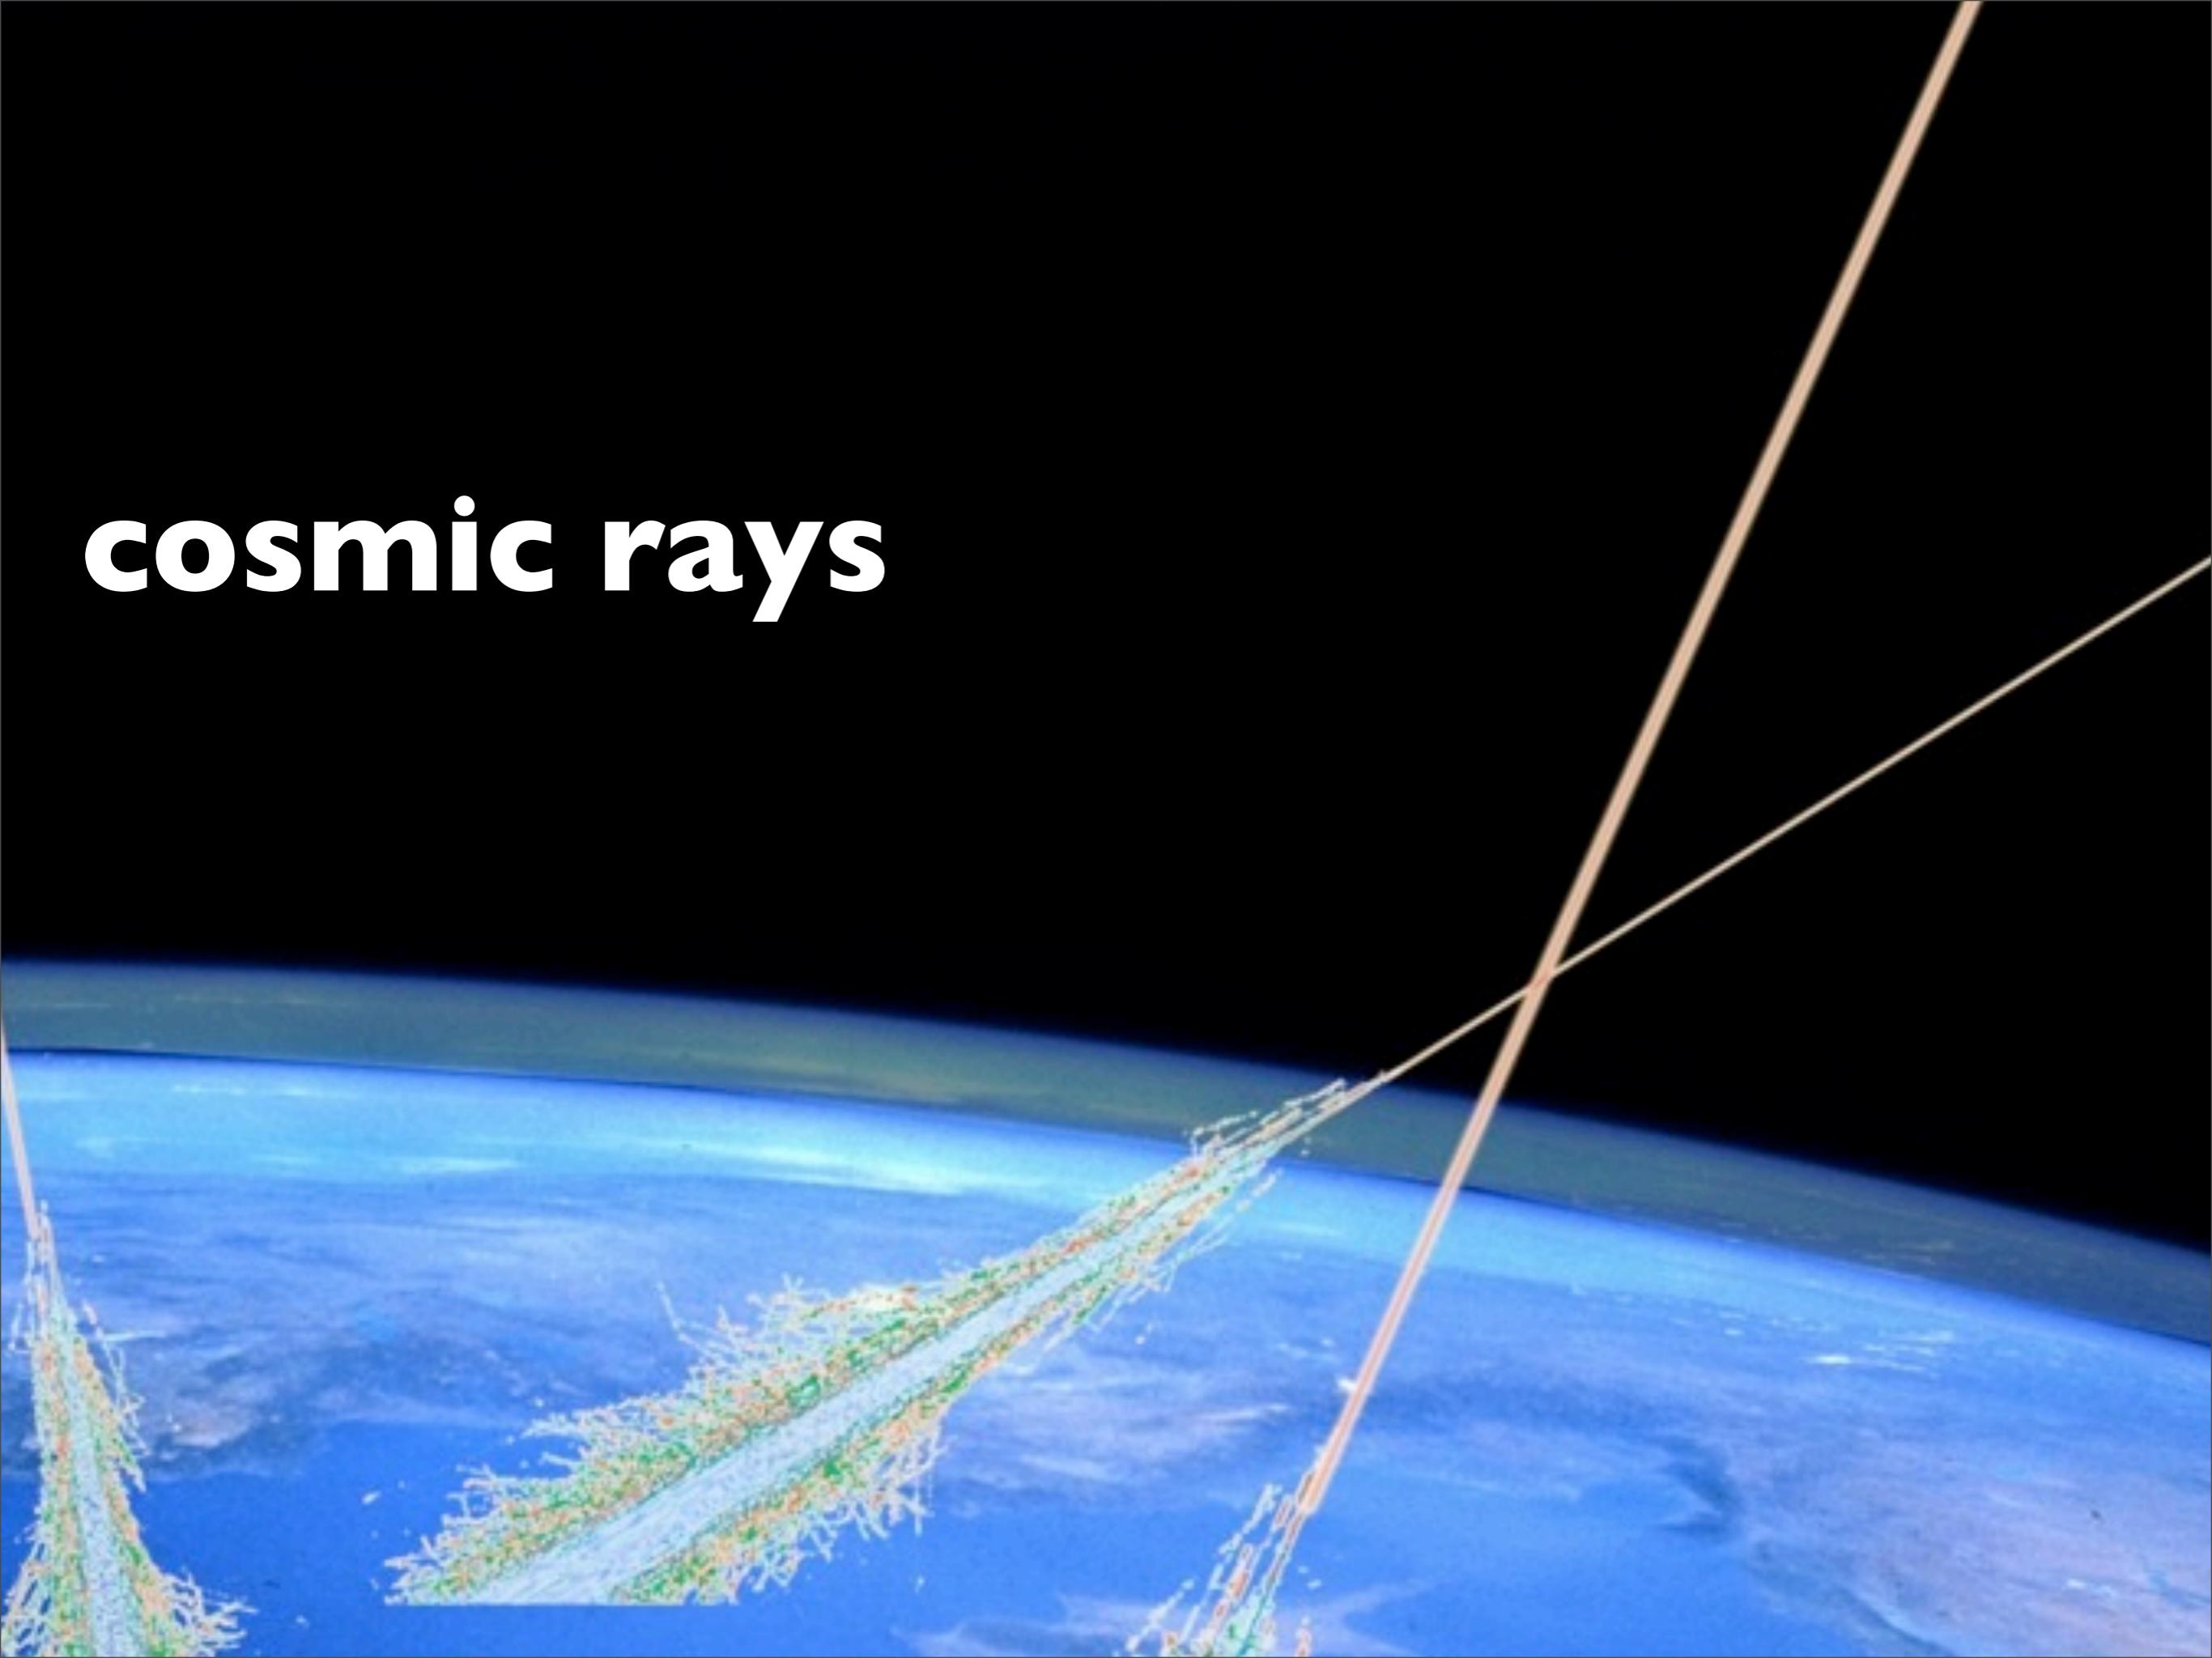

Jansson & Farrar model - total field

Jansson & Farrar, *ApJ* 757 (2012) 14

Jansson & Farrar *ApJL* 761 (2012) L11

cosmic rays

ultra-high energy cosmic rays (UHECRs)

fundamental questions

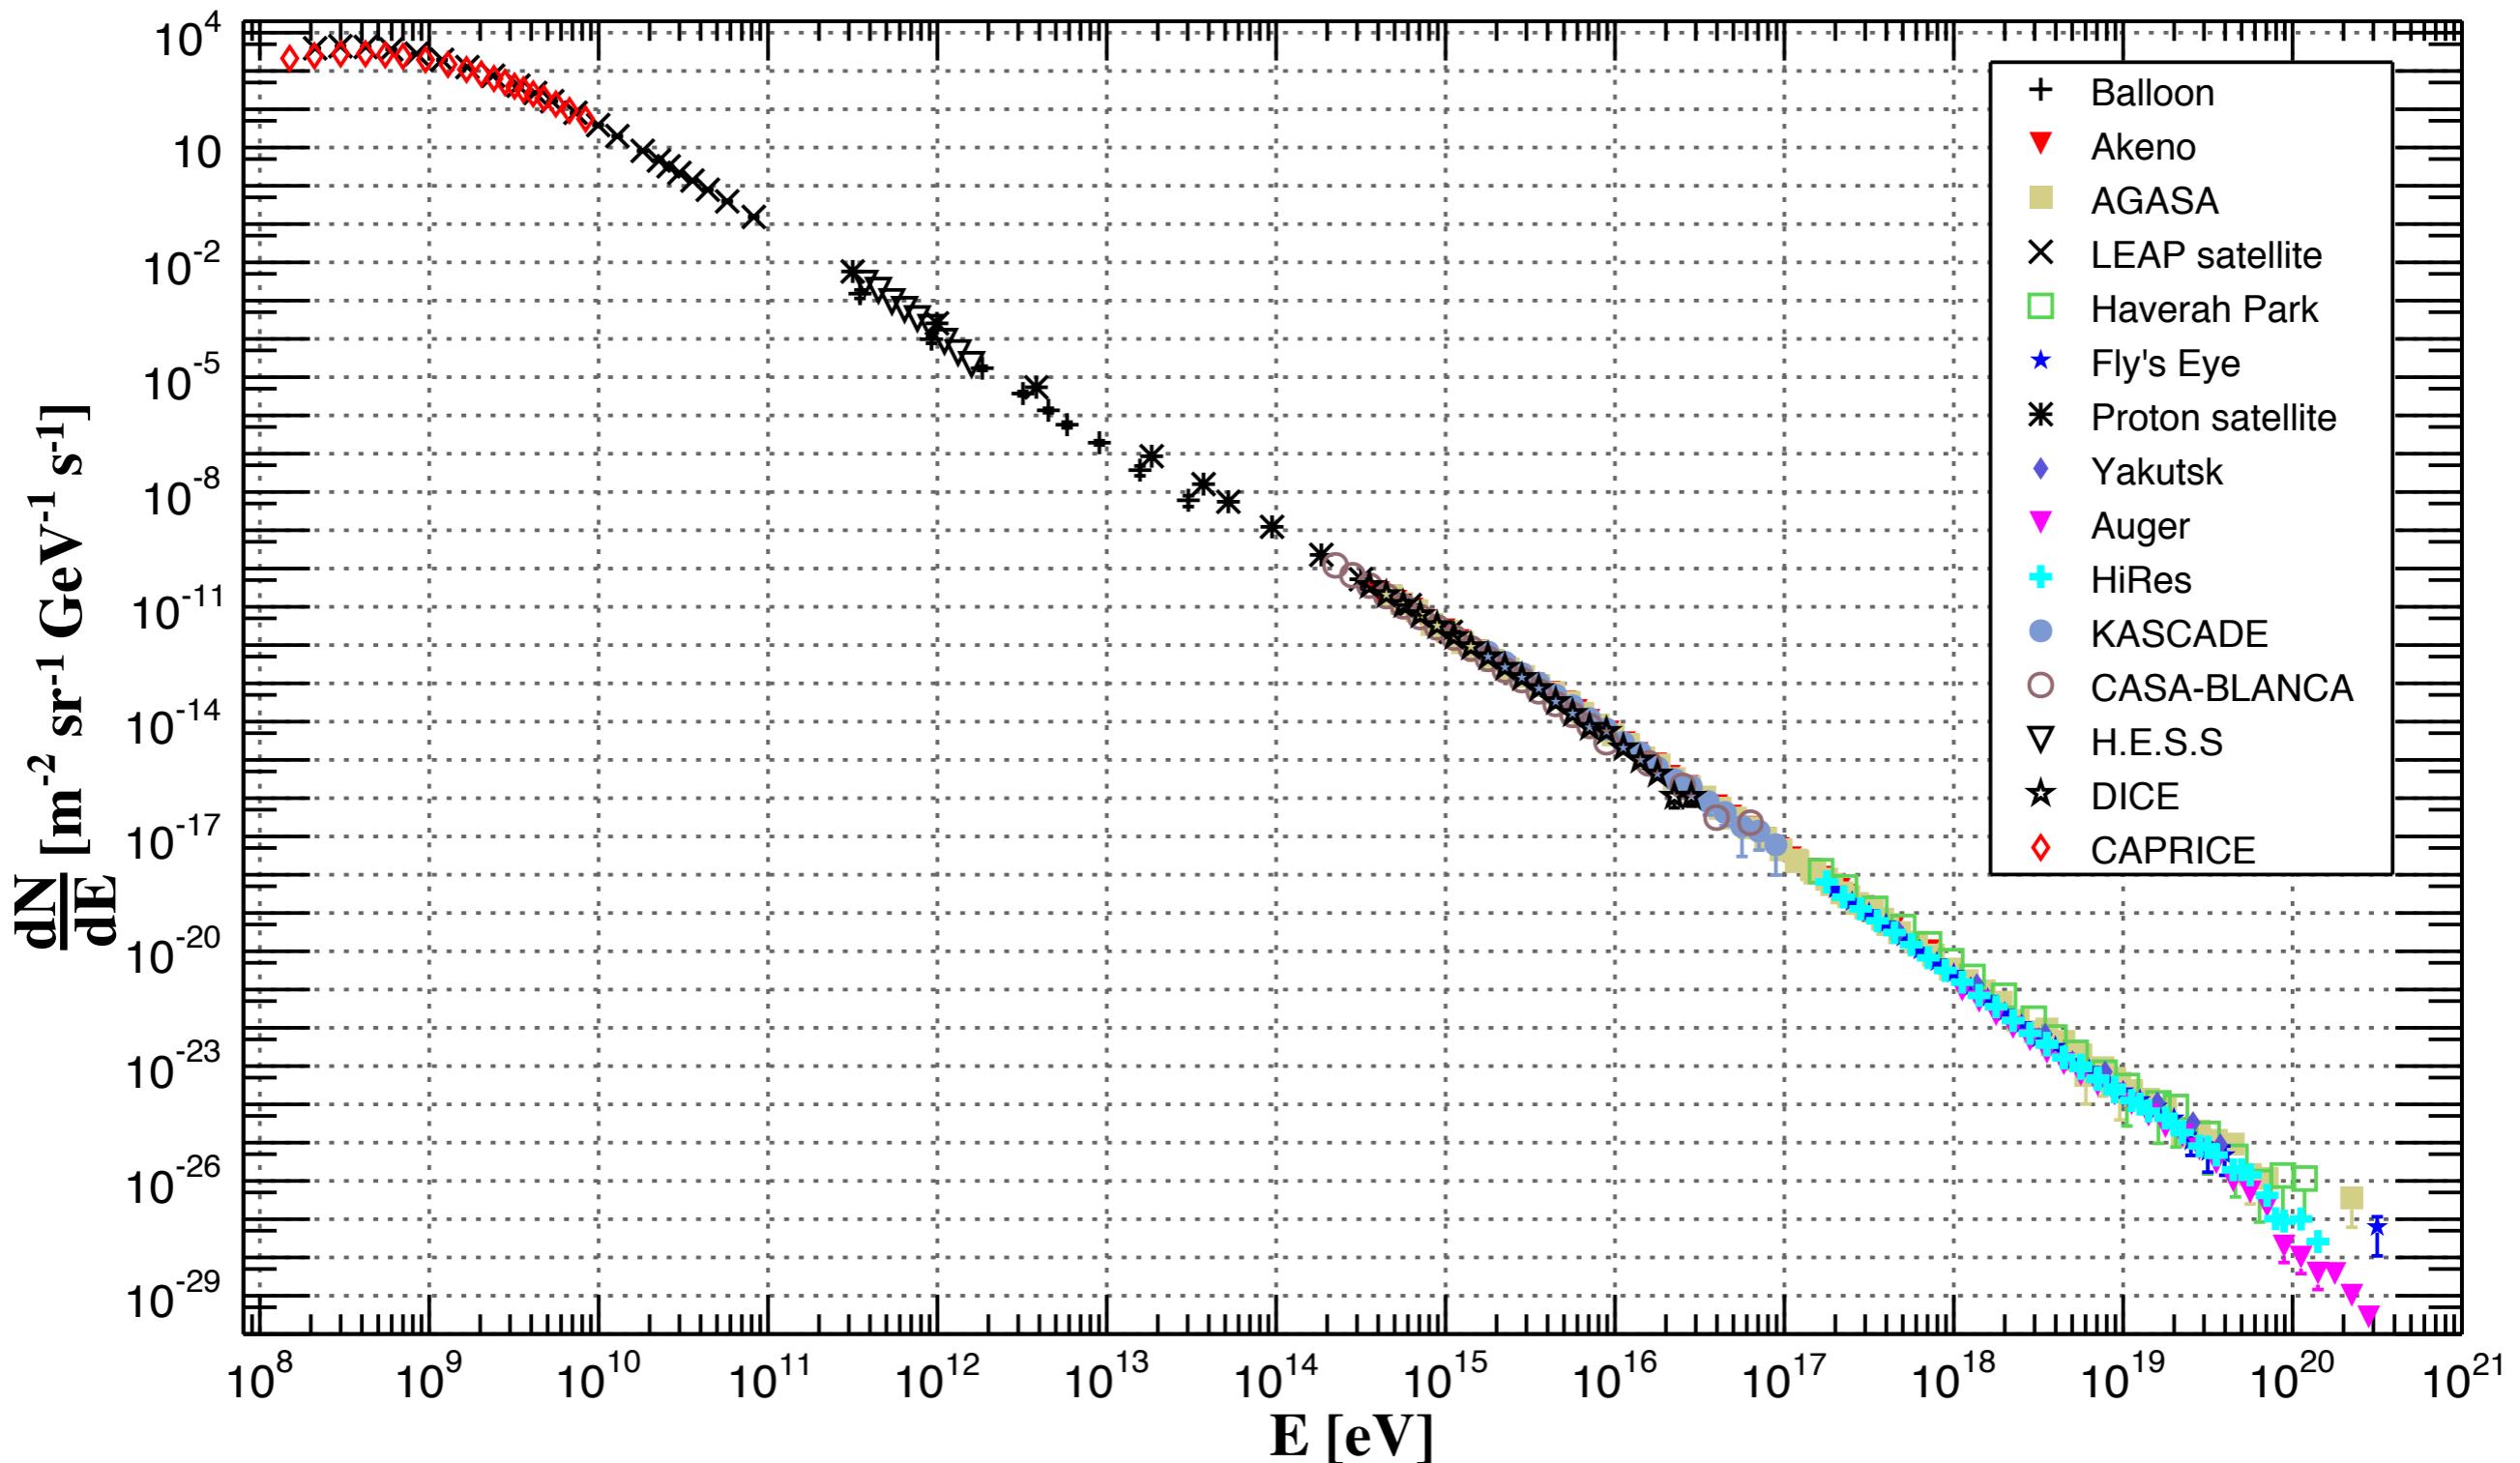

- ▶ where do they come from?
- ▶ what are they made of?
- ▶ how are they accelerated?

some problems

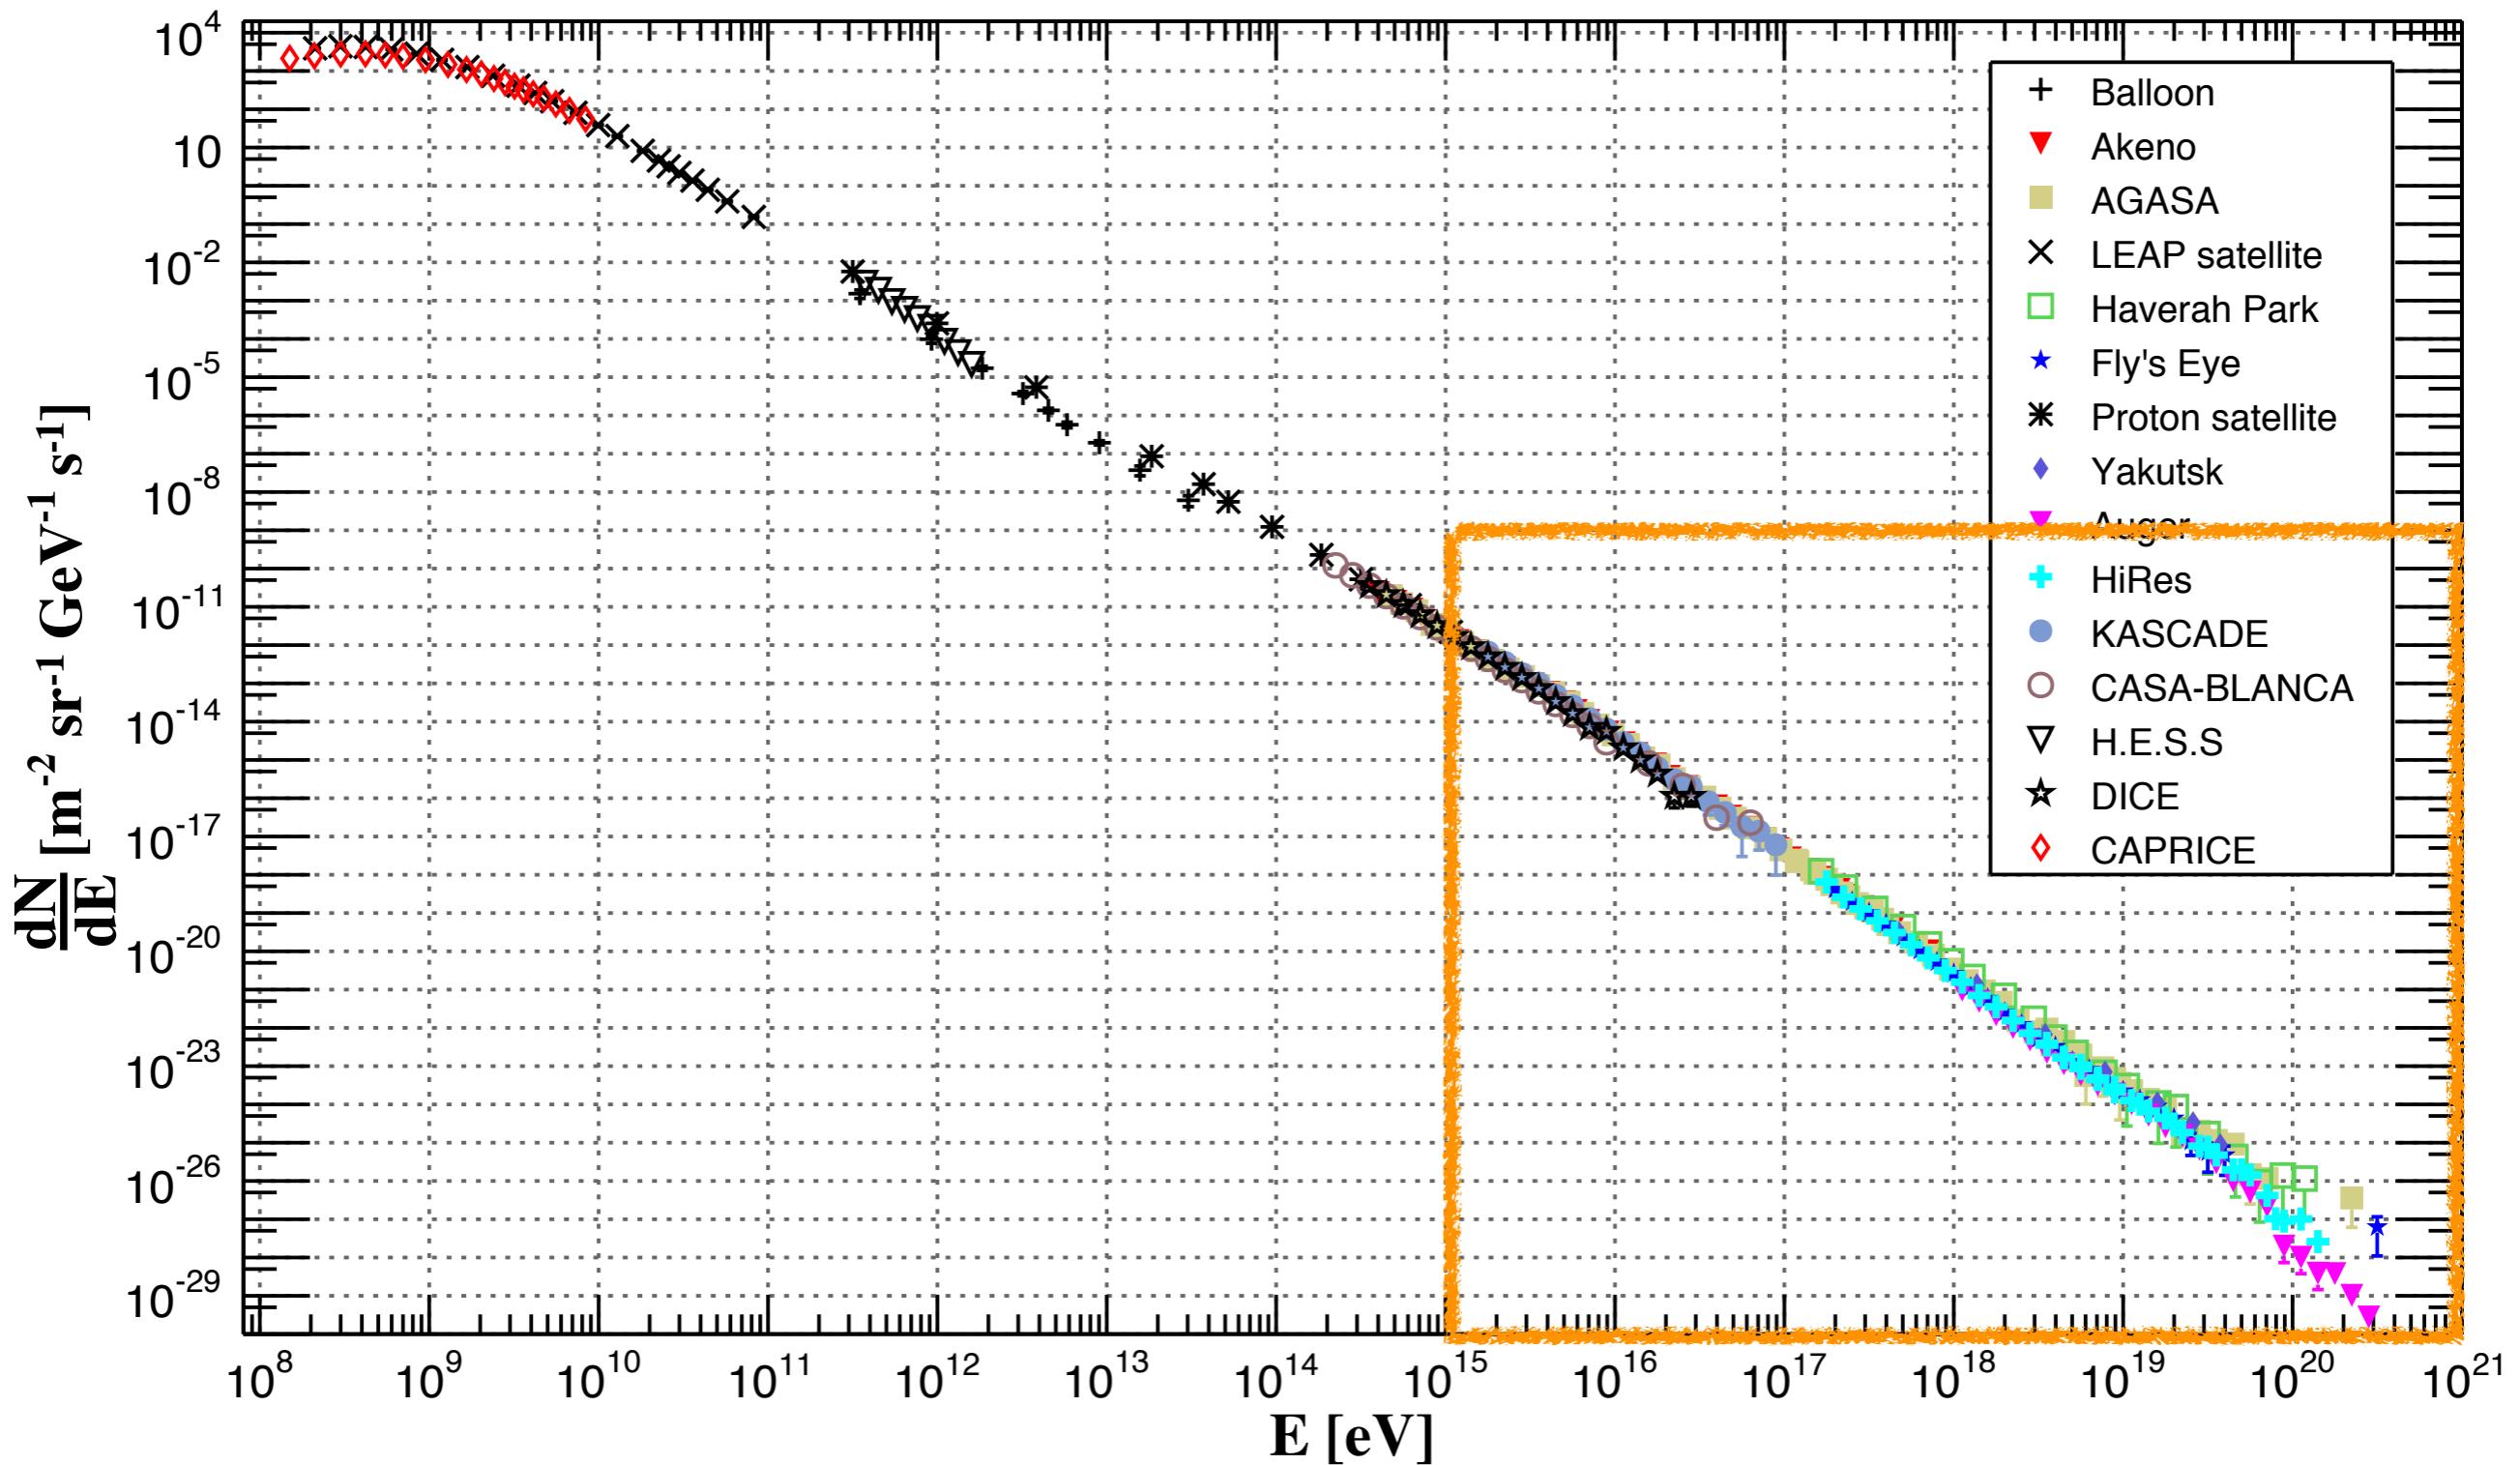

- ▶ what is the maximum energy they can reach?
- ▶ do we see a GZK cutoff
- ▶ where does the transition between galactic and extragalactic cosmic rays take place?
- ▶ where does the transition between diffusive and ballistic regimes happen?

- ▶ observables from CR experiments: spectrum, composition, anisotropy
- ▶ cosmic magnetic fields (galactic and extragalactic) are important
- ▶ test new physics scenarios using UHECRs

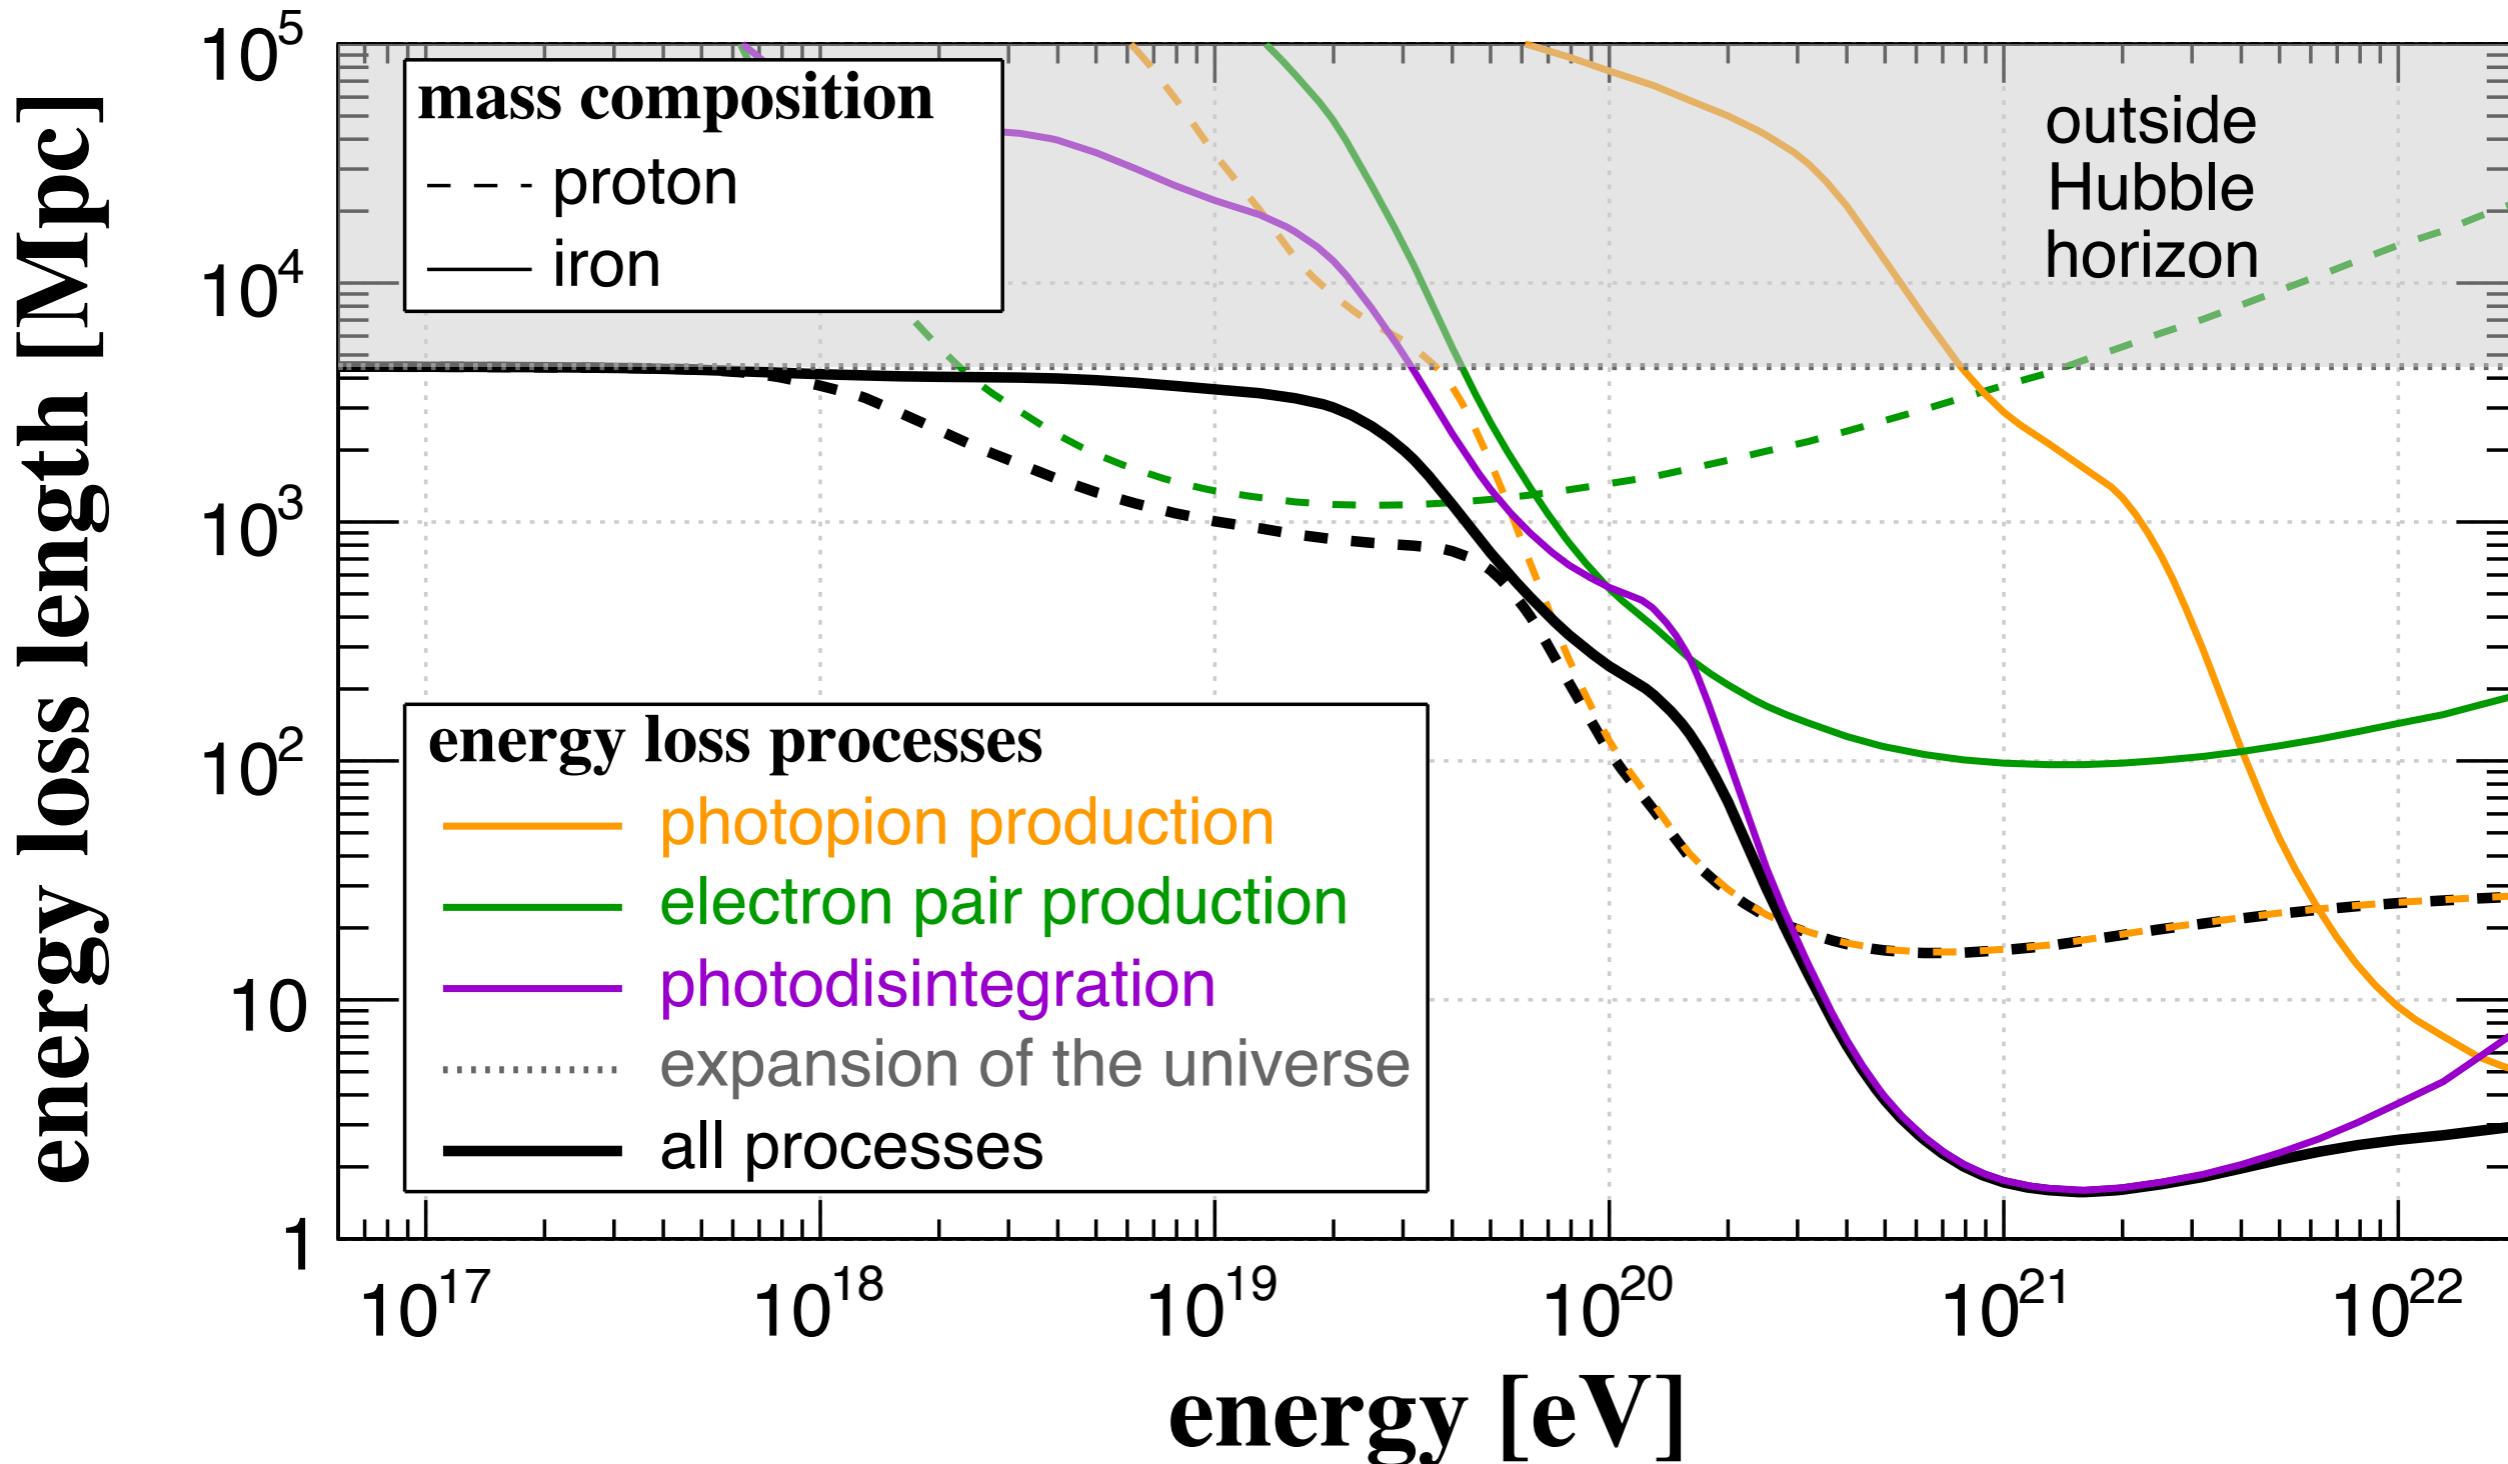

the cosmic ray spectrum

the cosmic ray spectrum

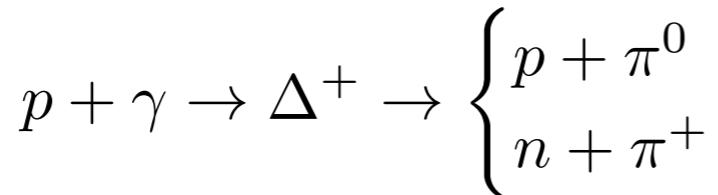

interactions and energy loss processes

interactions and energy loss processes

**photopion
production**

mean free path for nuclei written as a function
of the mfp for protons and neutrons

**expansion of the
universe**

$$\frac{dt}{dz} = \frac{1}{H_0} \frac{1}{1+z} \frac{1}{\sqrt{\Omega_m(1+z)^3 + \Omega_\Lambda}} \quad E = \frac{E_0}{1+z} \quad \Lambda\text{CDM cosmology}$$

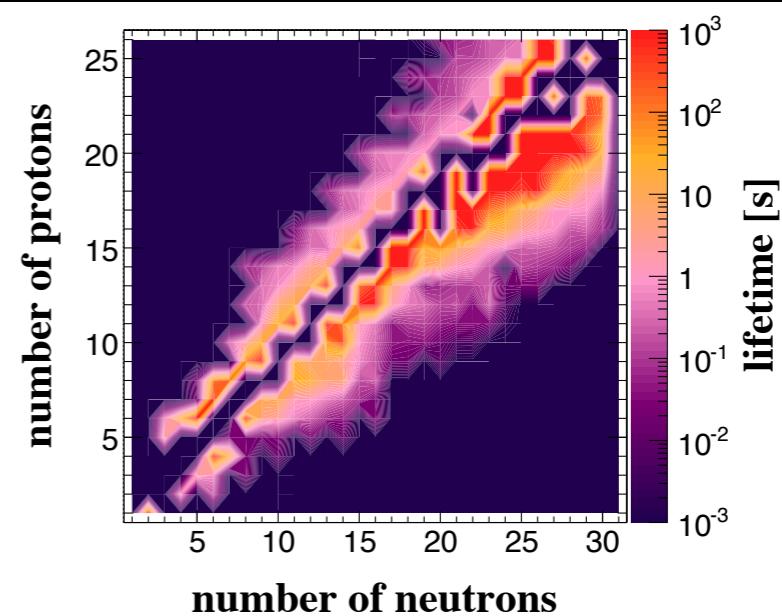

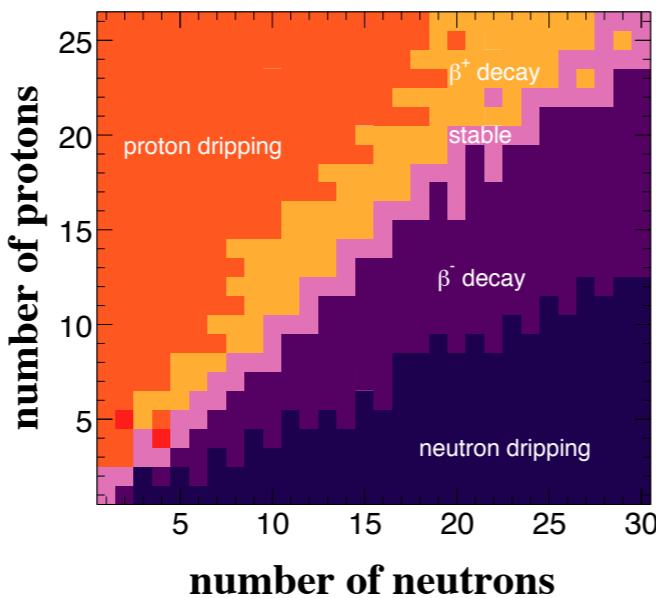

pair production

$$-\frac{dE_{A,Z}}{dt} = 3\alpha\sigma_T h^{-3} Z^2 m_e c^2 k_B T f(\Gamma)$$

photodisintegration

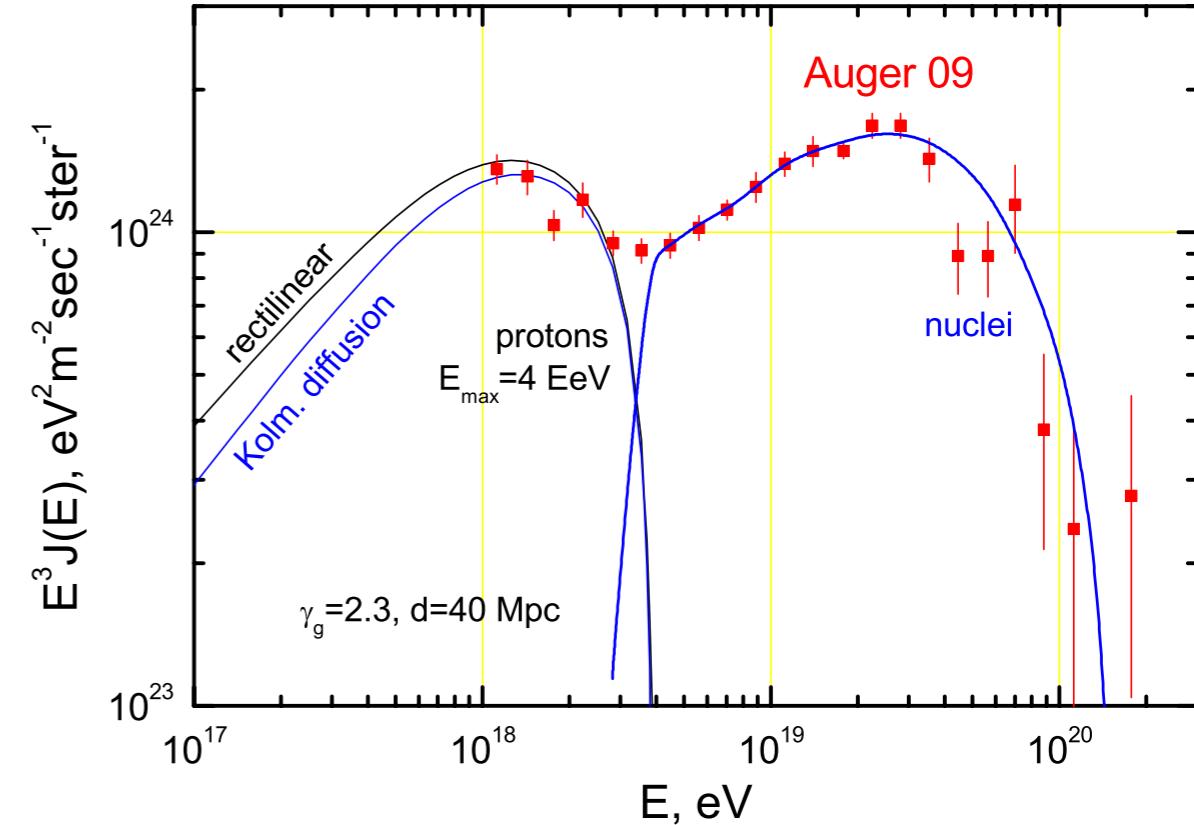

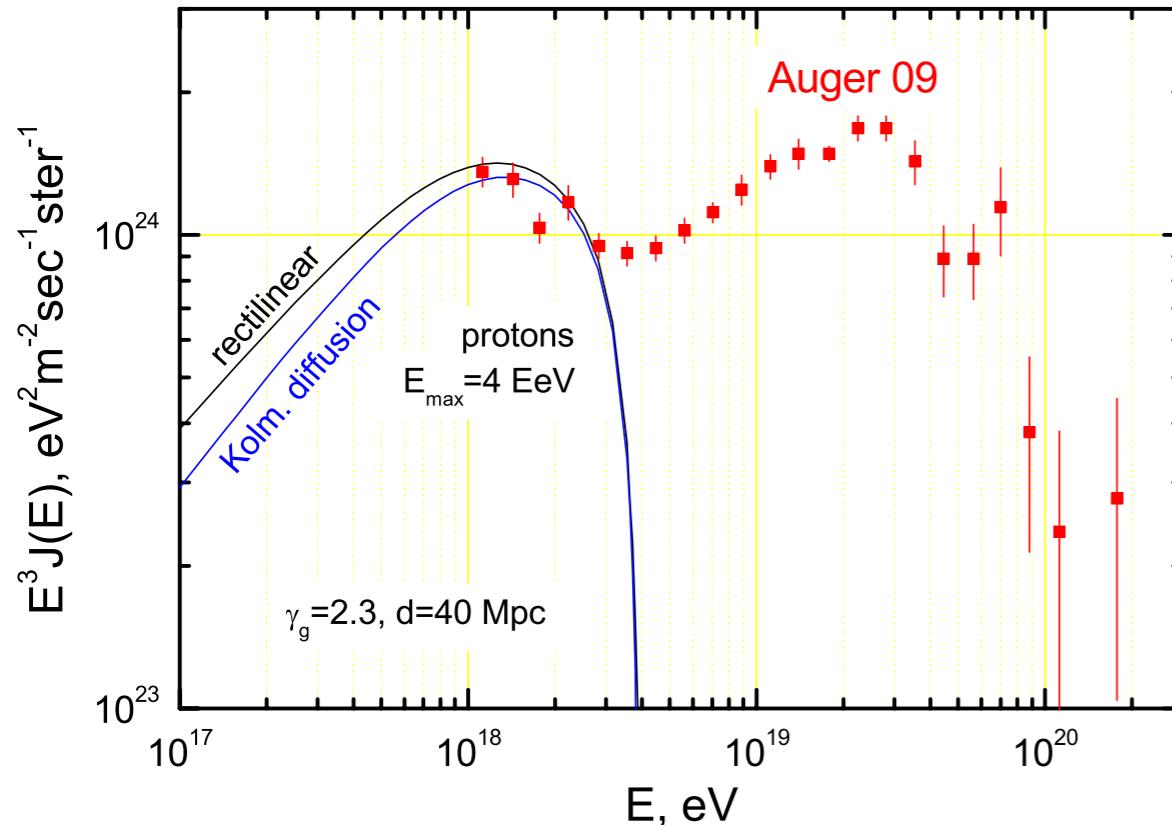

$$\frac{1}{\lambda(\Gamma)} = \int_{E_{min}}^{E_{max}} n(\epsilon, z) \bar{\sigma}(\epsilon'_{max} = 2\Gamma\epsilon) d\epsilon$$

nuclear decay

the “disappointing” model

Aloisio et al., Astropart. Phys. 34
(2011) 620

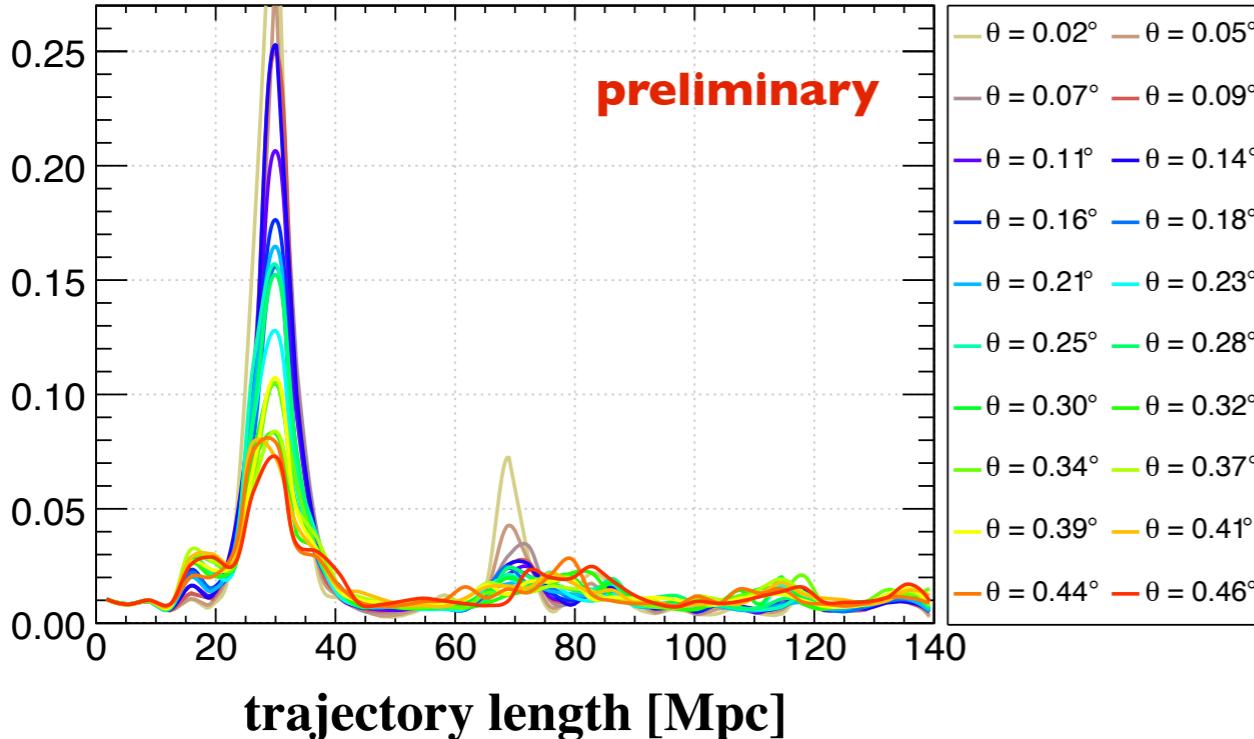

- ▶ highest energy cutoff due to maximum acceleration of sources
- ▶ no GZK effect

deflections in extragalactic magnetic fields

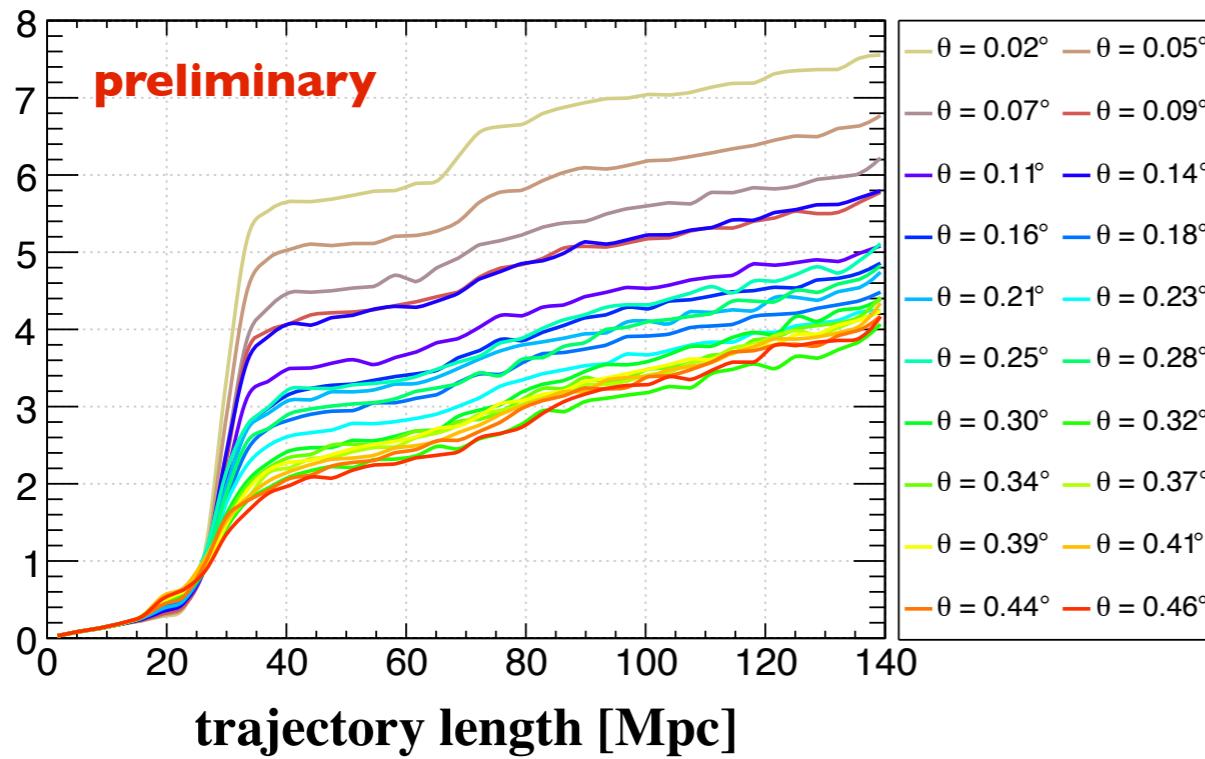

RAB, J. Devriendt, D. Semikoz, M.-S. Shin, G. Sigl. In preparation.

deflection [degrees]

trajectory length [Mpc]

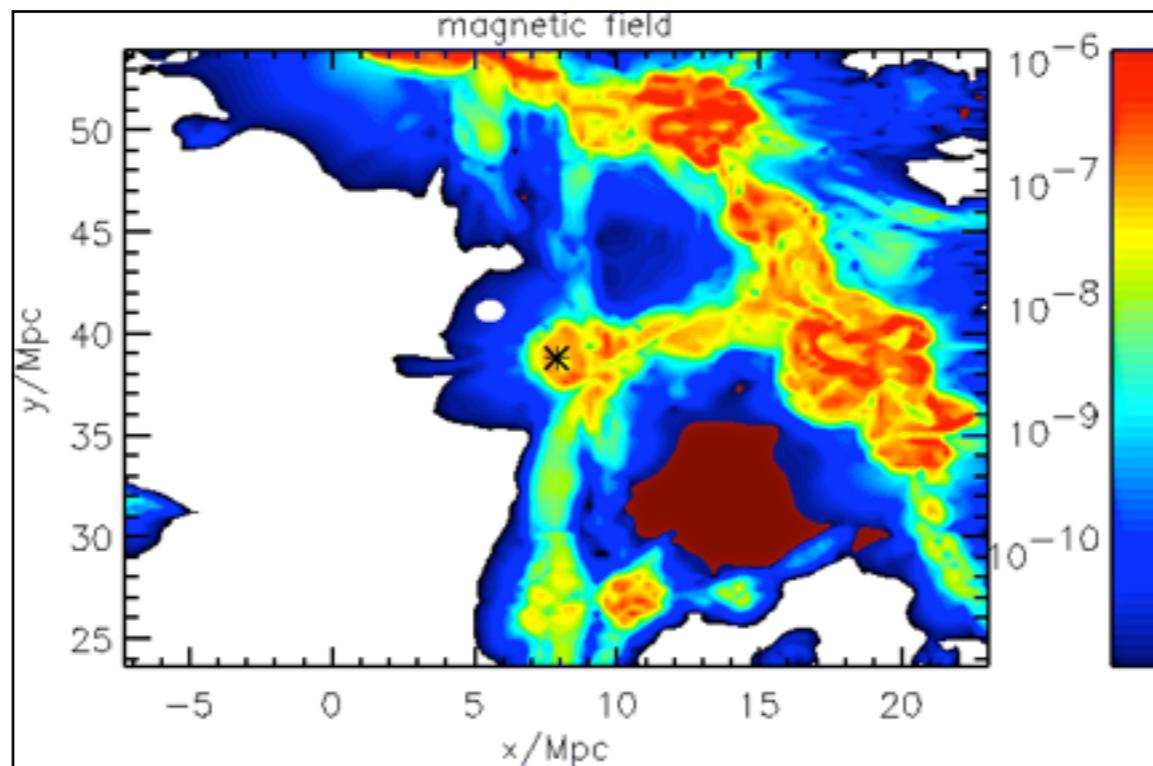

cumulative deflection [degrees]

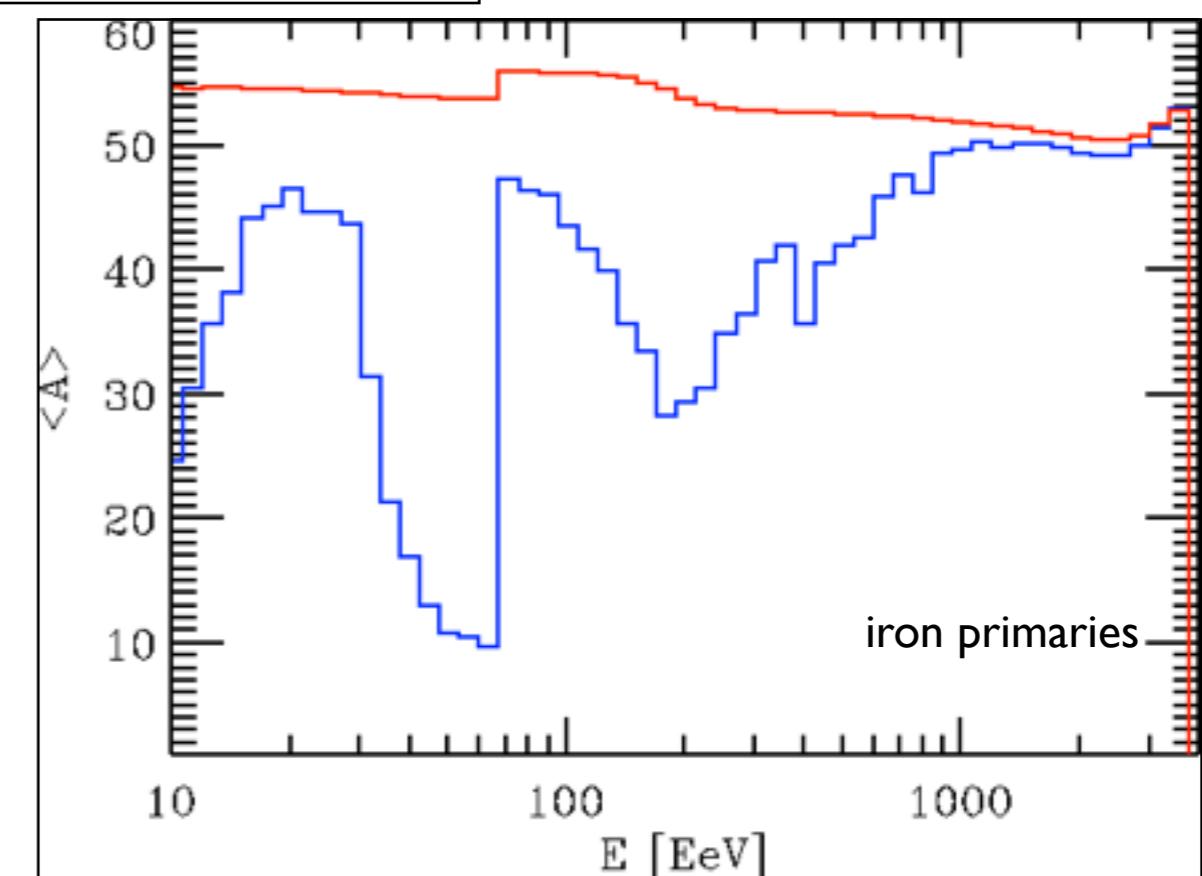

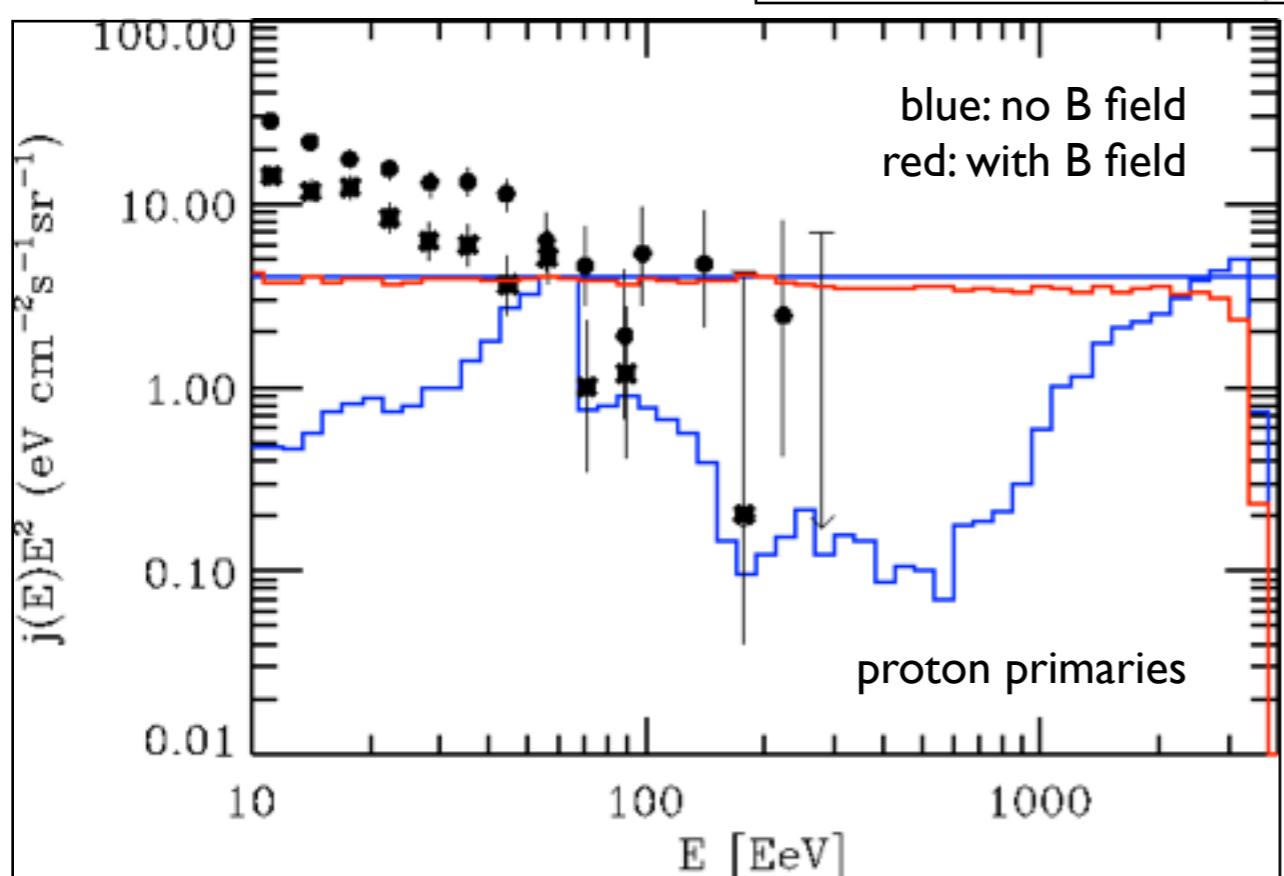

trajectory length [Mpc]

- ▶ UHECR “tomography”
- ▶ simulation of events recording its full trajectory, changing its initial angle within a cone of θ
- ▶ the average over 100 realization for each angle is plotted
- ▶ high deflections observed when particles cross structures
- ▶ useful for cross checks
- ▶ size of the structure is given by the angle of the cone in which the deflections start to become small, and the size (trajectory length) around peaks

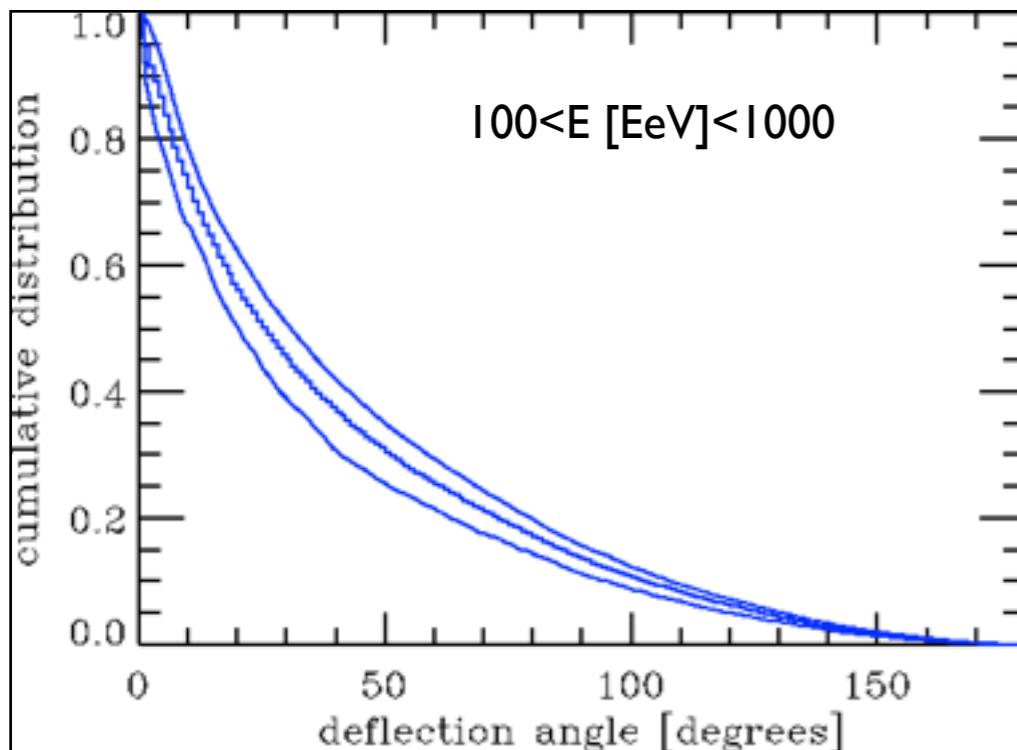

UHECRs from individual sources

Sigl. JCAP 08 (2004) 012

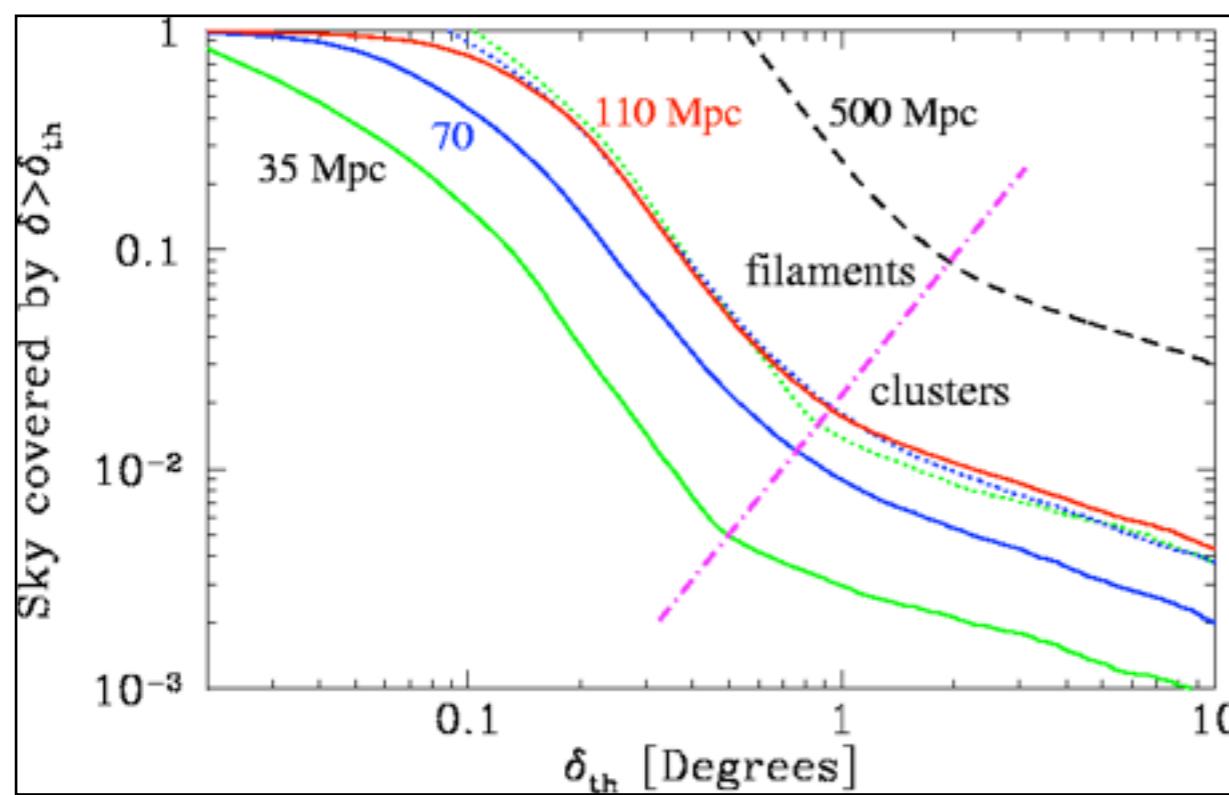

UHECR astronomy?

Sigl, Miniati, Ensslin. PRD 70
(2004) 043007

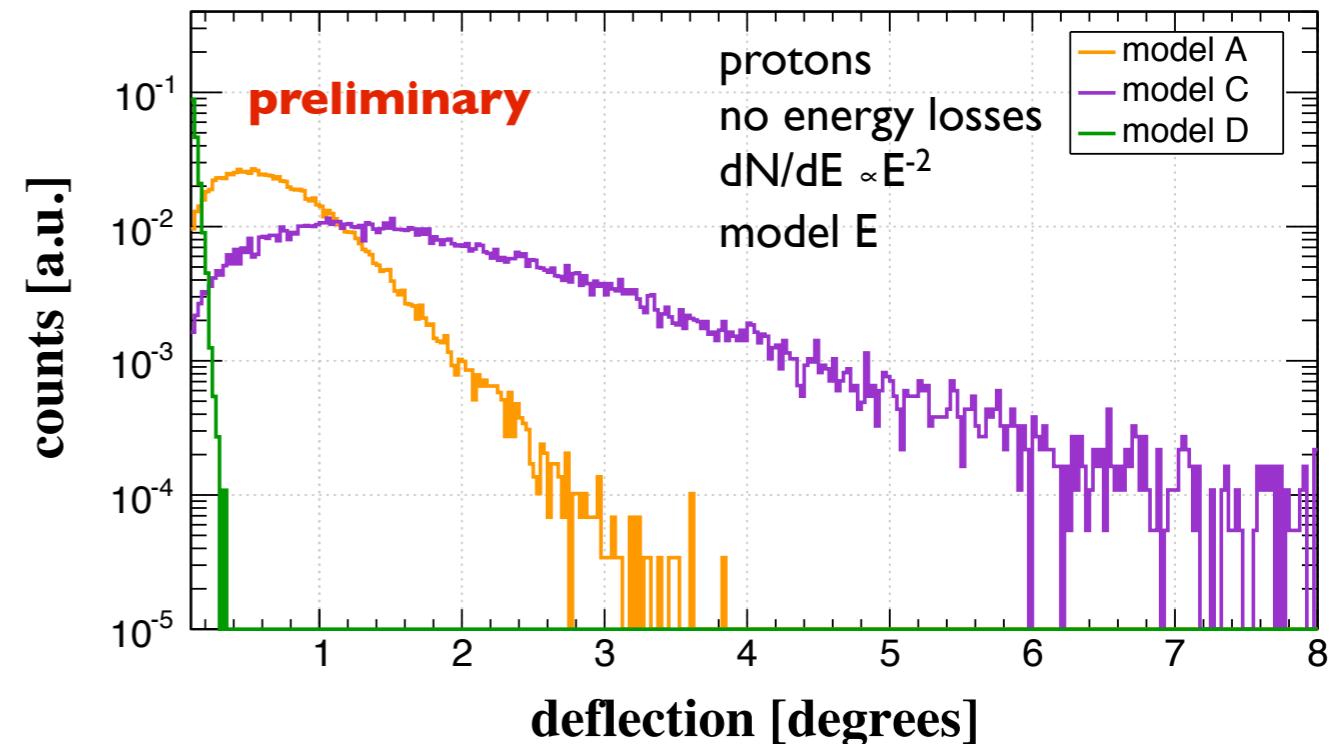

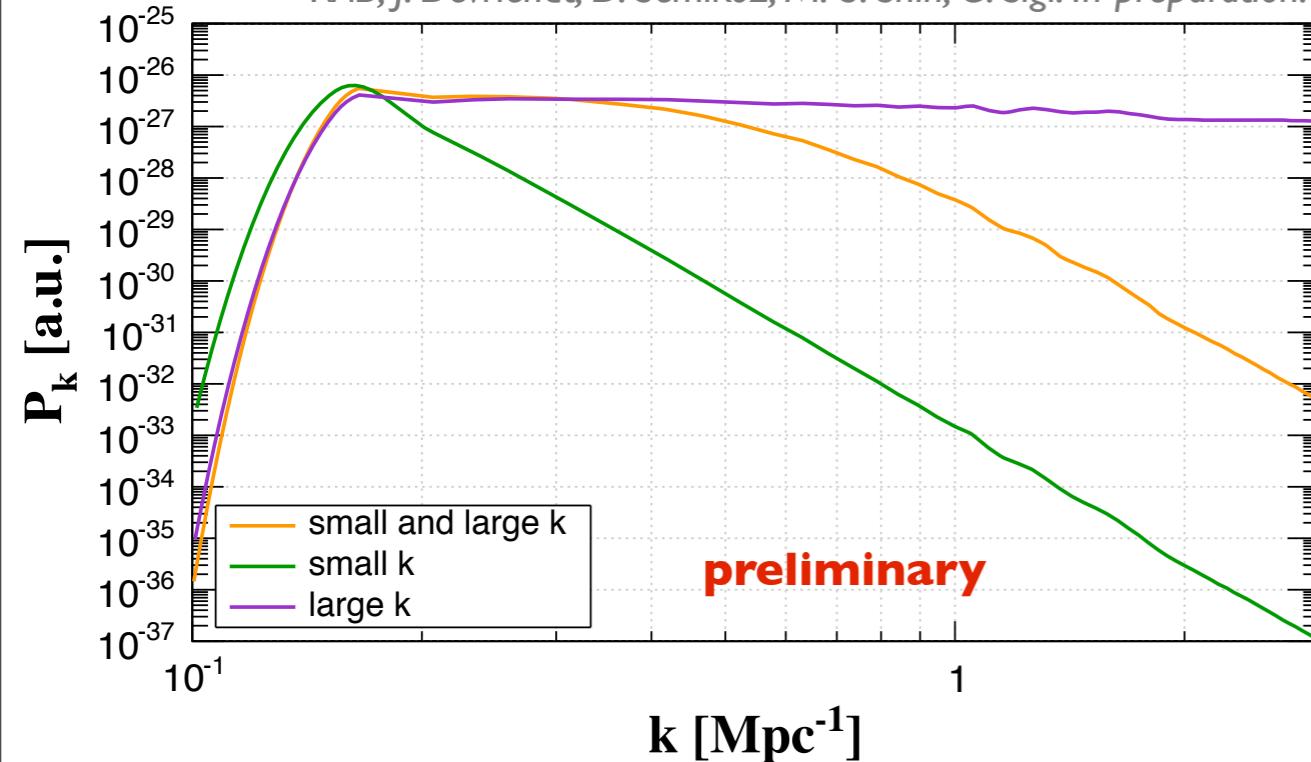

- ▶ cumulative deflections displayed are for protons
- ▶ Sigl+: deflections are high
- ▶ Dolag+: deflections are small
- ▶ for heavy nuclei deflections can be even higher
- ▶ UHECR astronomy may be possible in the later but not in the former scenario

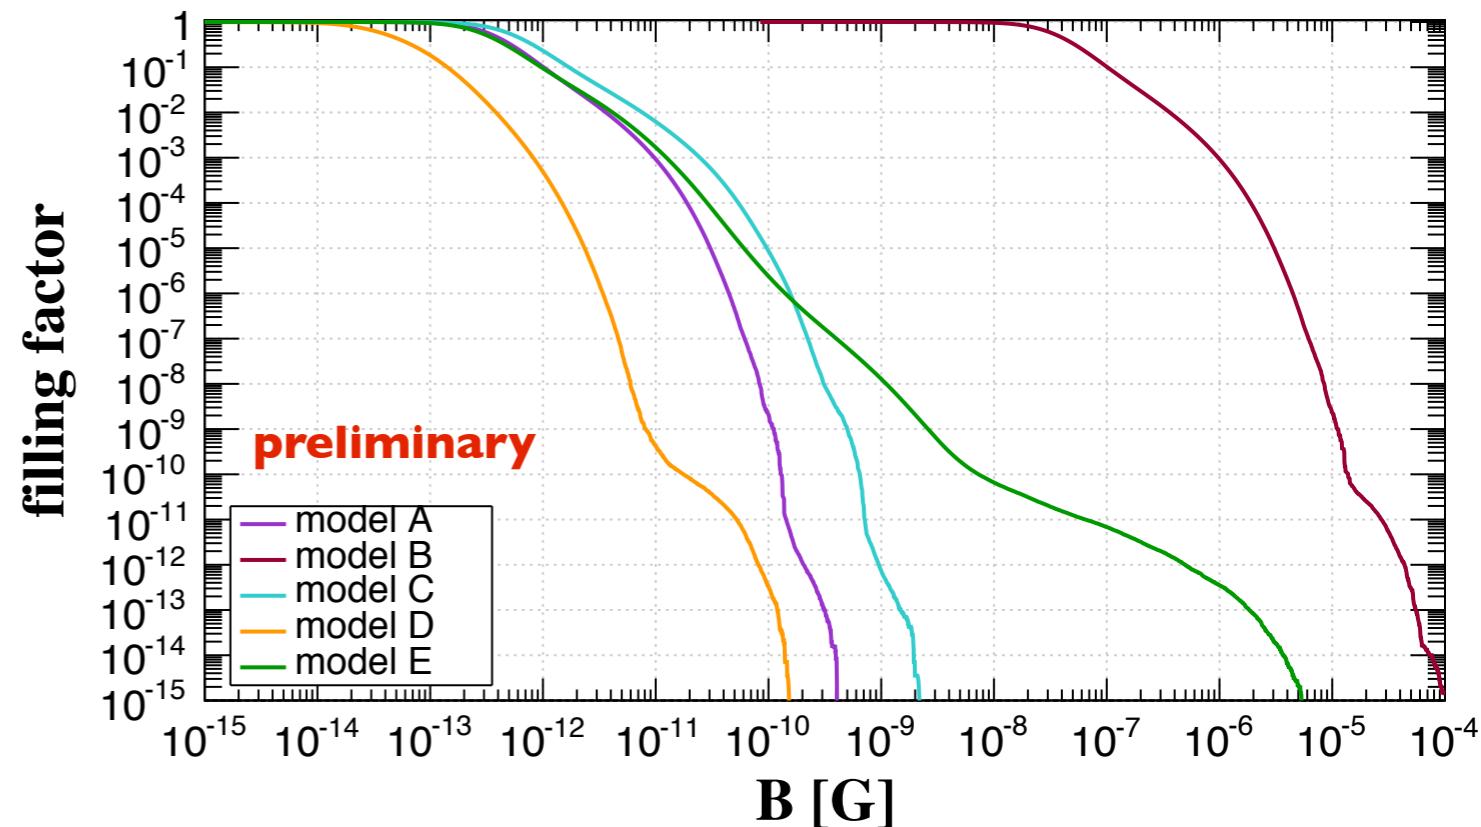

Dolag et al. JETP 79(2004) 583

UHECR astronomy?

RAB, J. Devriendt, D. Semikoz, M.-S. Shin, G. Sigl. In preparation.

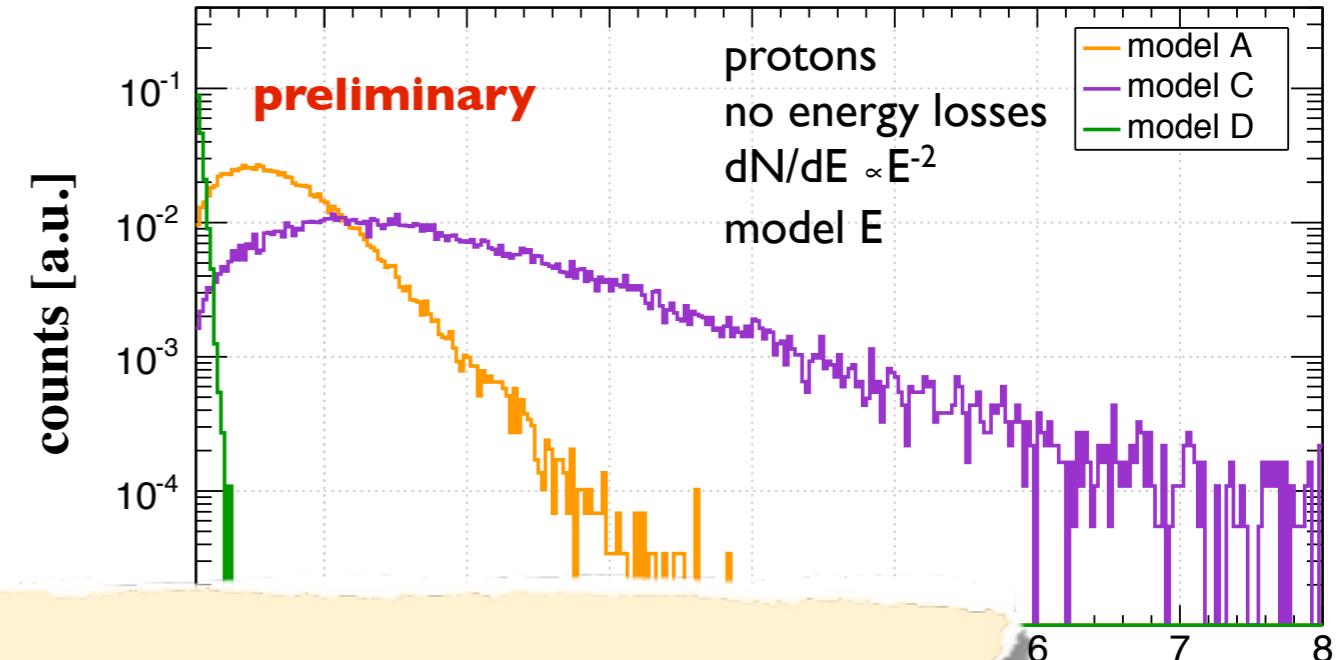

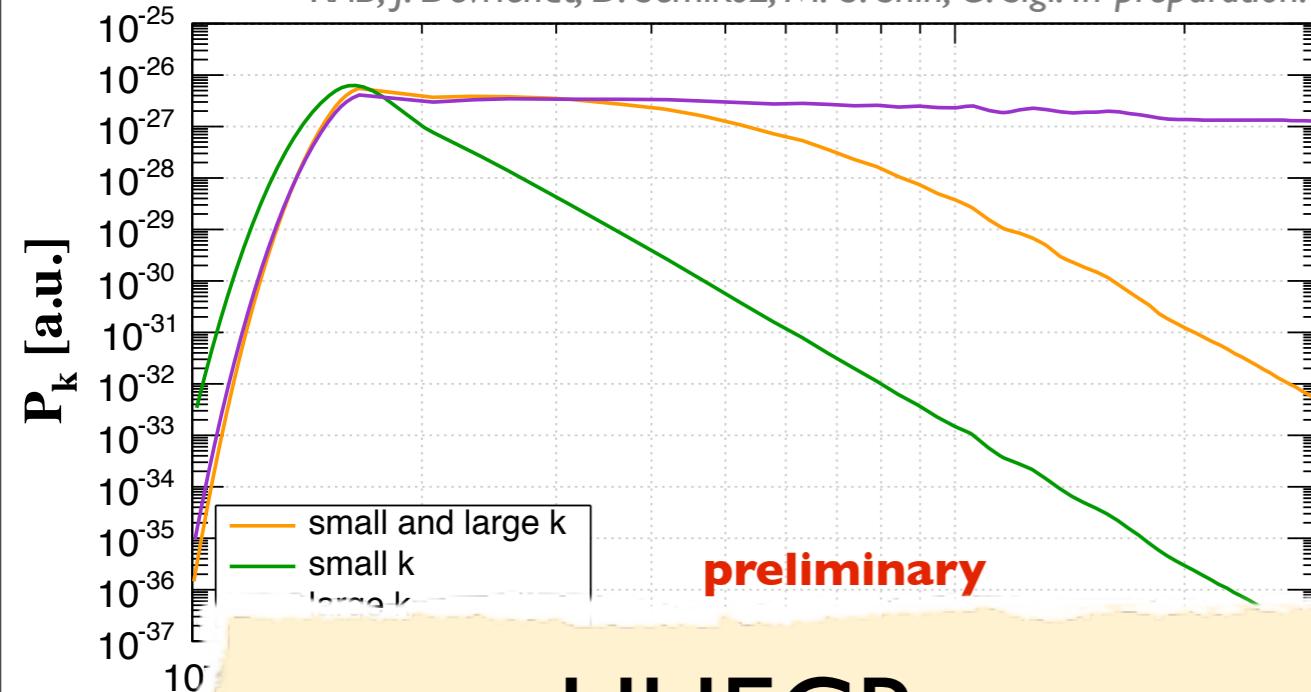

- ▶ 200 Mpc/h box
- ▶ simulations being done by M.-S. Shin, J. Devriendt, ...
- ▶ adaptative mesh refinement (AMR) using the RAMSES code [Teyssier '02]
- ▶ 10 levels of refinement

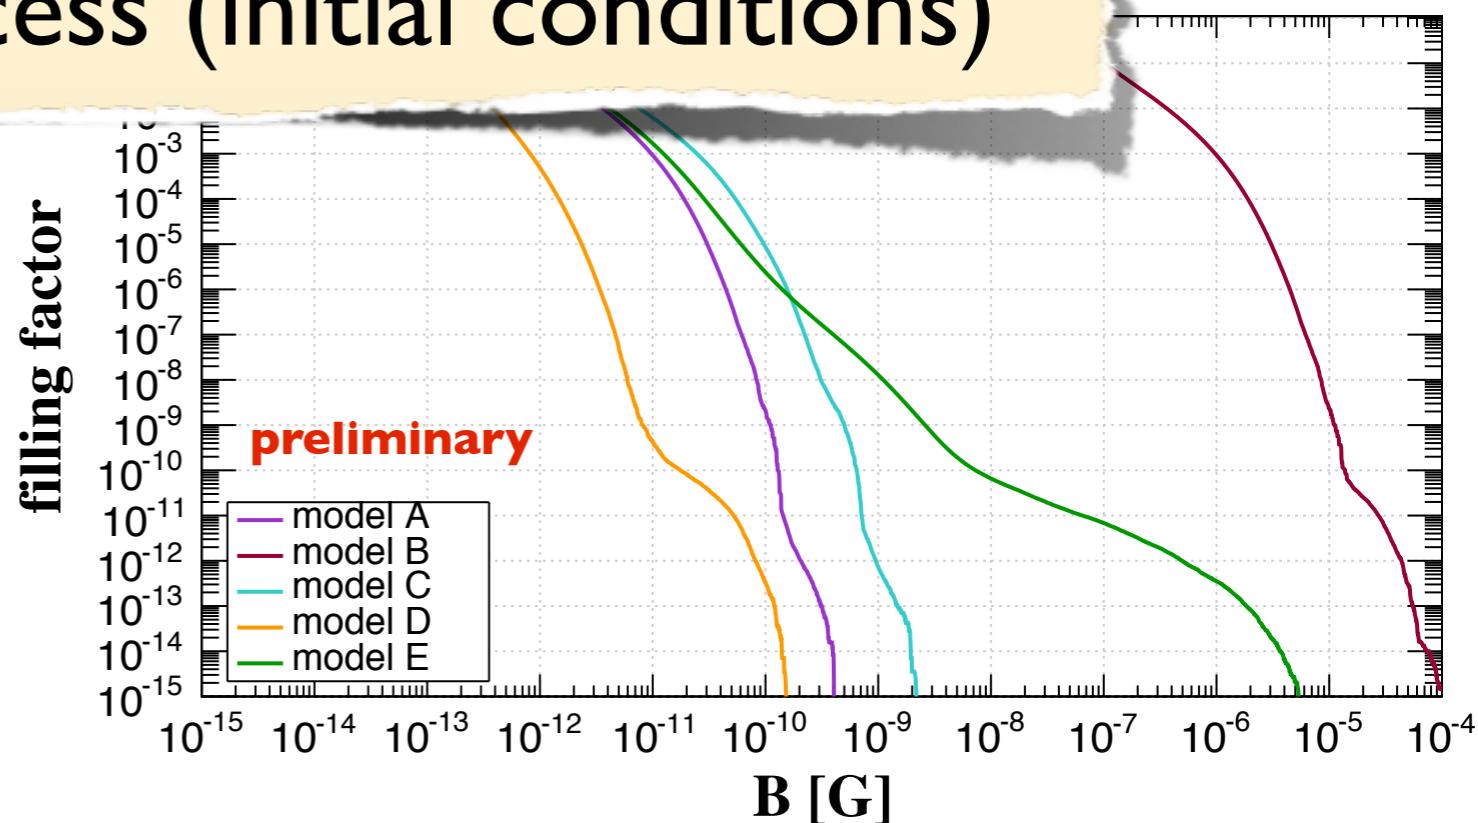

UHECR astronomy?

RAB, J. Devriendt, D. Semikoz, M.-S. Shin, G. Sigl. In preparation.

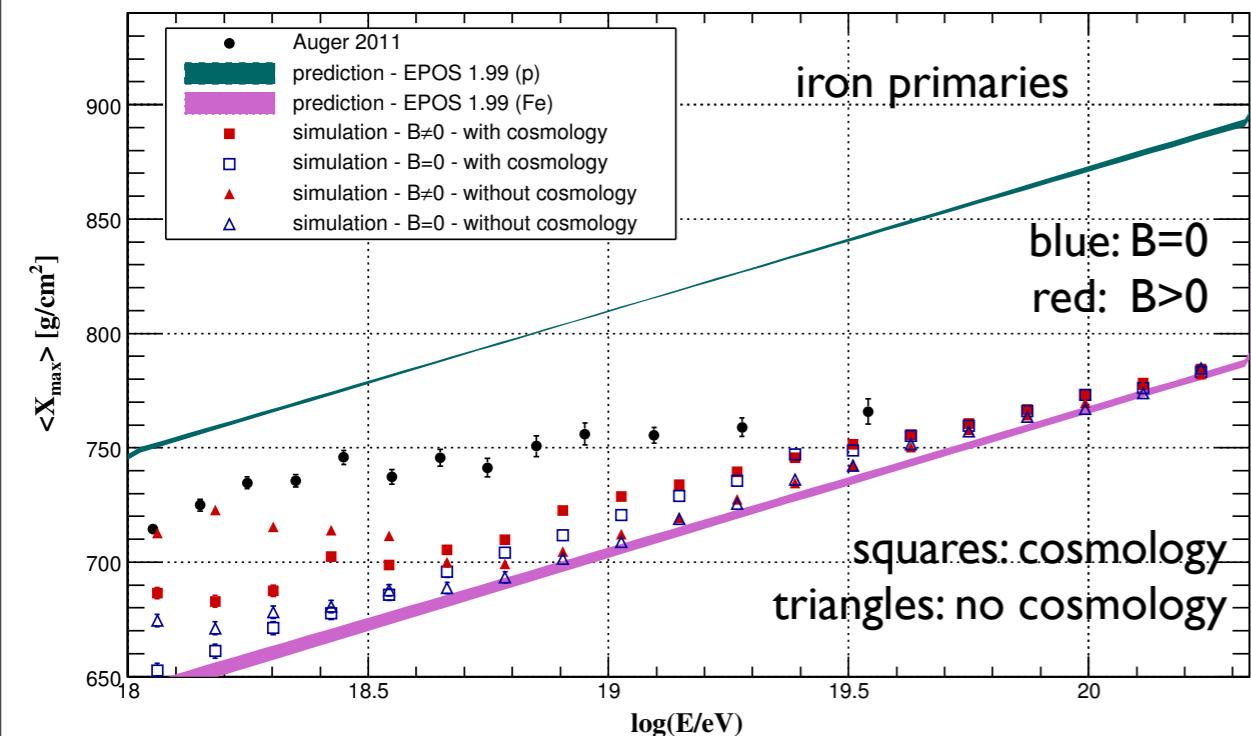

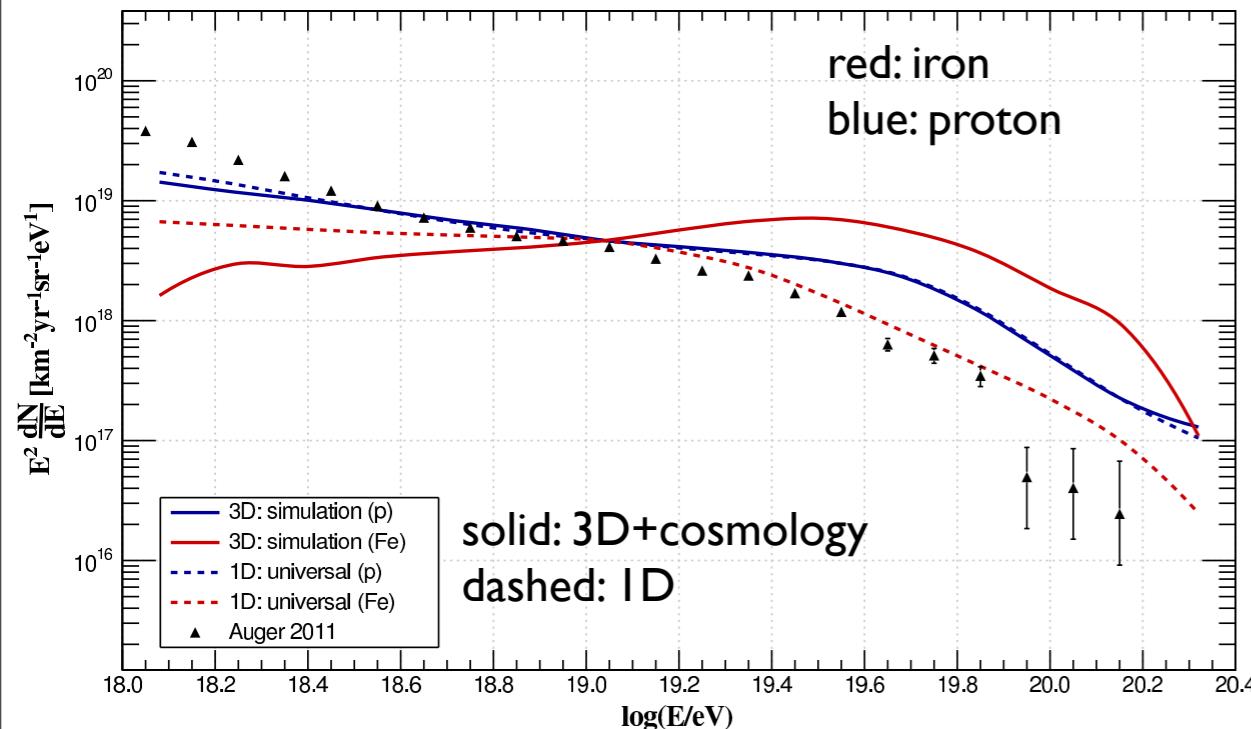

UHECR astronomy depends on
magnetogenesis process (initial conditions)

- ▶ 200 Mpc/h box
- ▶ simulations being done by M.-S. Shin, J. Devriendt, ...
- ▶ adaptative mesh refinement (AMR) using the RAMSES code [Teyssier '02]
- ▶ 10 levels of refinement

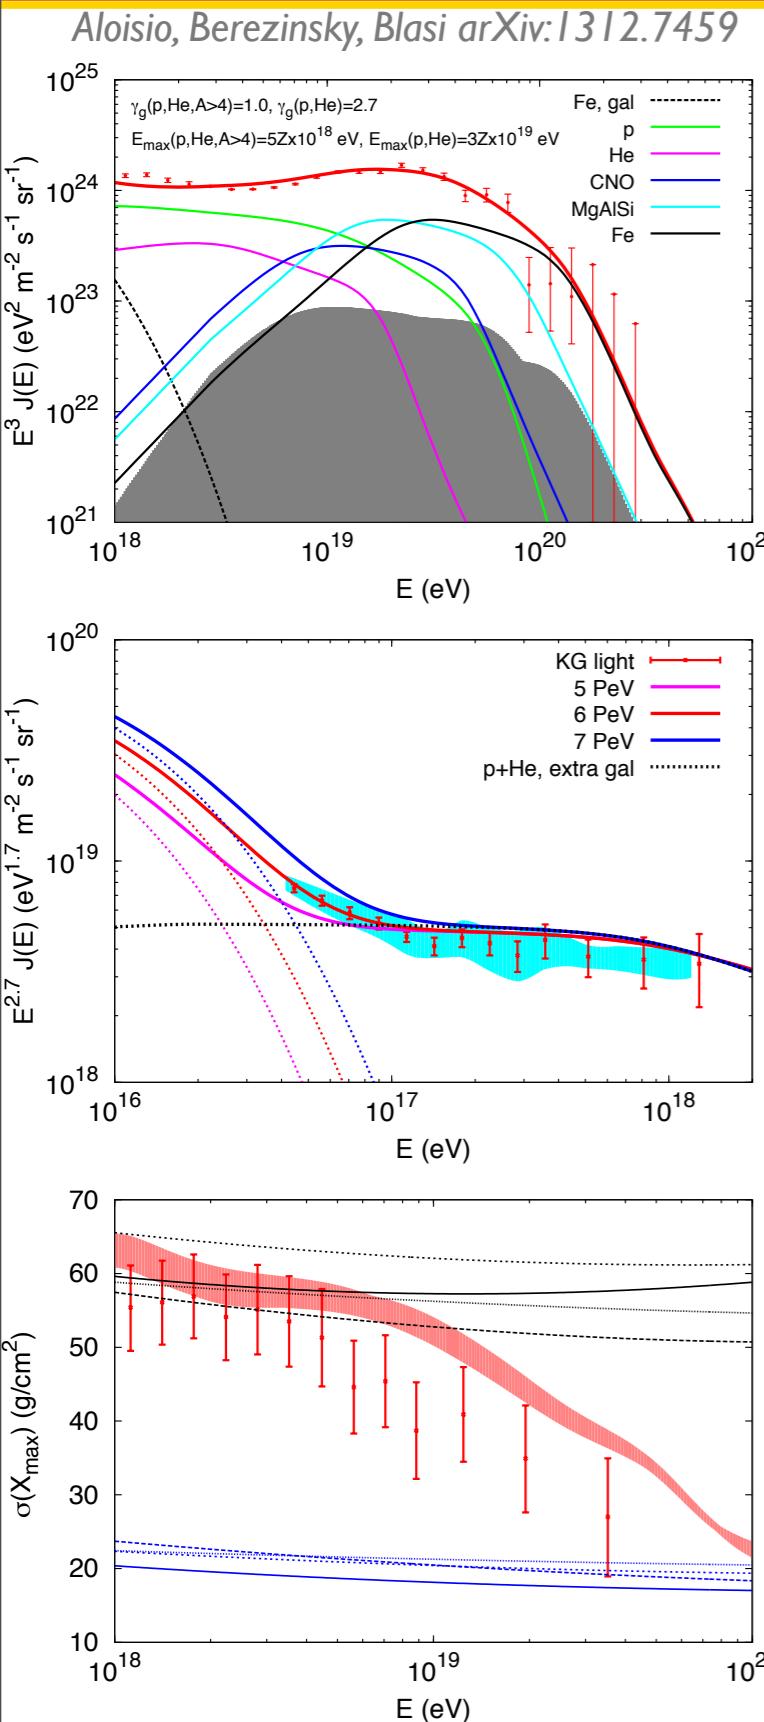

cosmological effects + magnetic fields

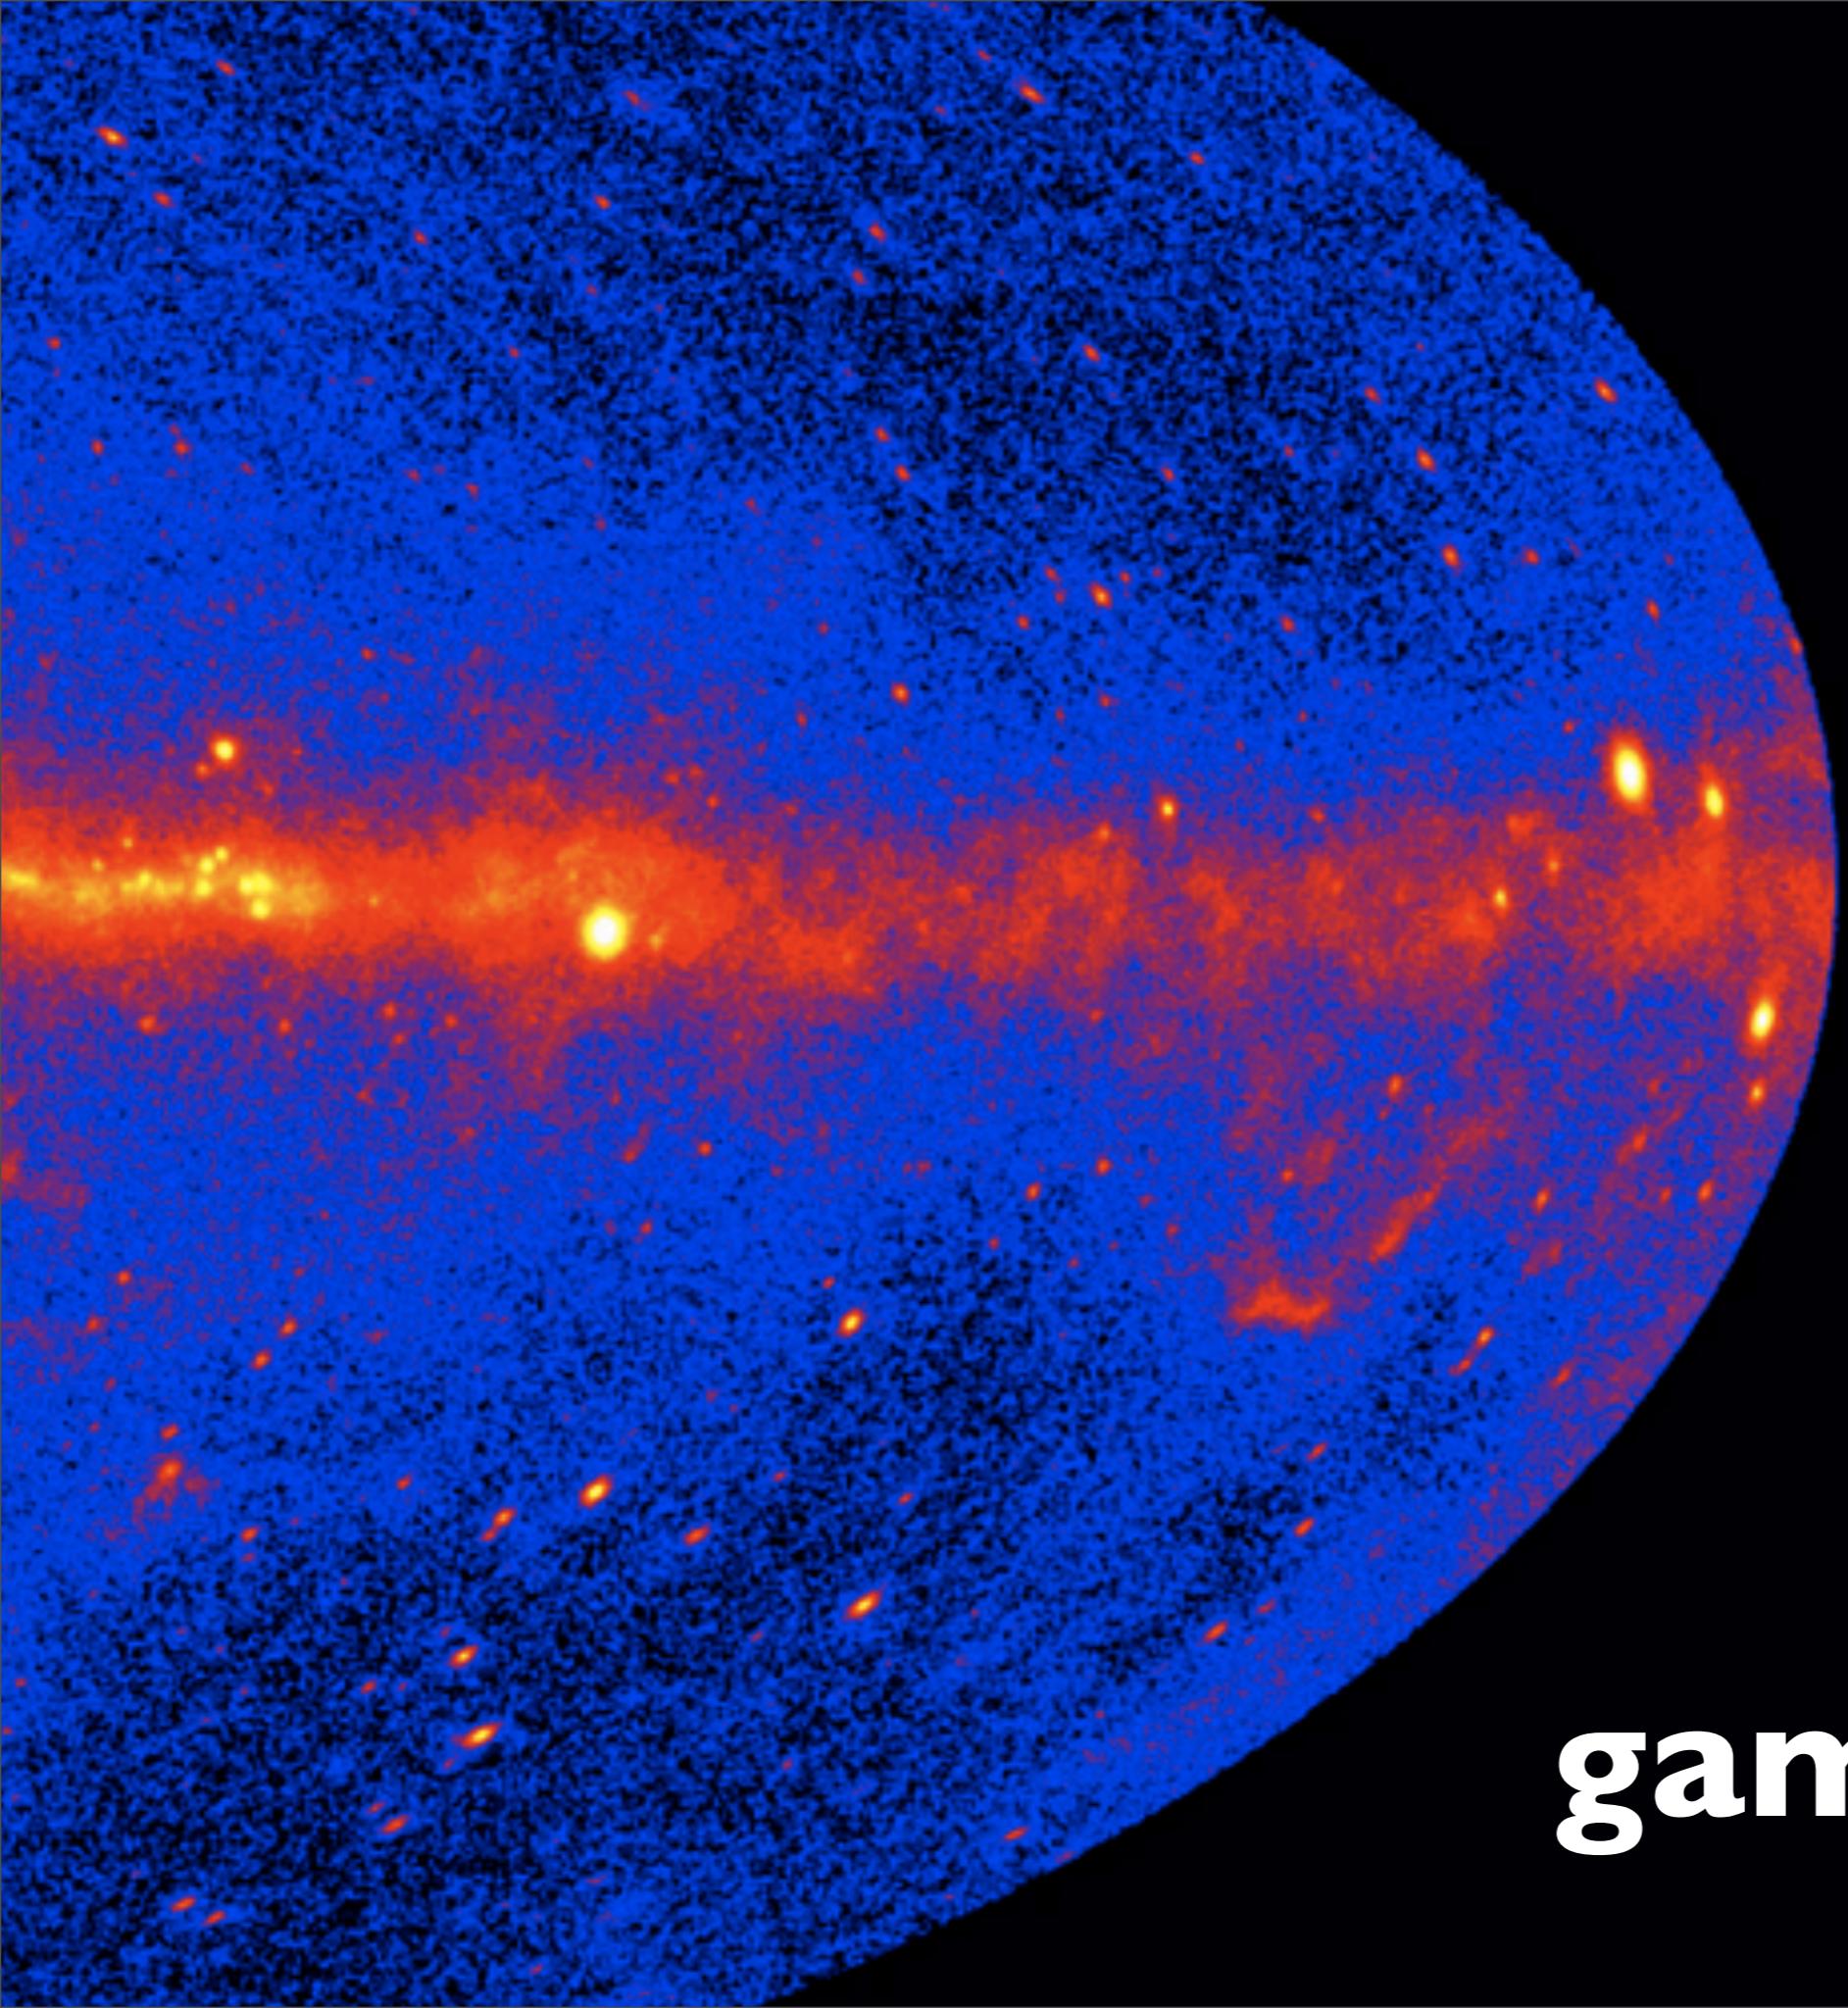

RAB, Schiffer, Sigl. NIMA 742 (2014) 245

- ▶ magnetic fields can affect the shape of the spectrum, so they should be taken into account when performing simulations text for one column no picture slide
- ▶ universal spectrum → expected for a uniform source distribution (separation << propagation lengths) → no magnetic field effects
- ▶ deviations from universal spectrum for pure iron composition
- ▶ large scale structures (magnetic field) + cosmological effects + energy losses → realistic simulations
- ▶ cosmological effects may be relevant, mainly at energies \sim EeV
- ▶ need to include cosmological effects in 3D simulations → 4D simulations

spectrum-composition fits

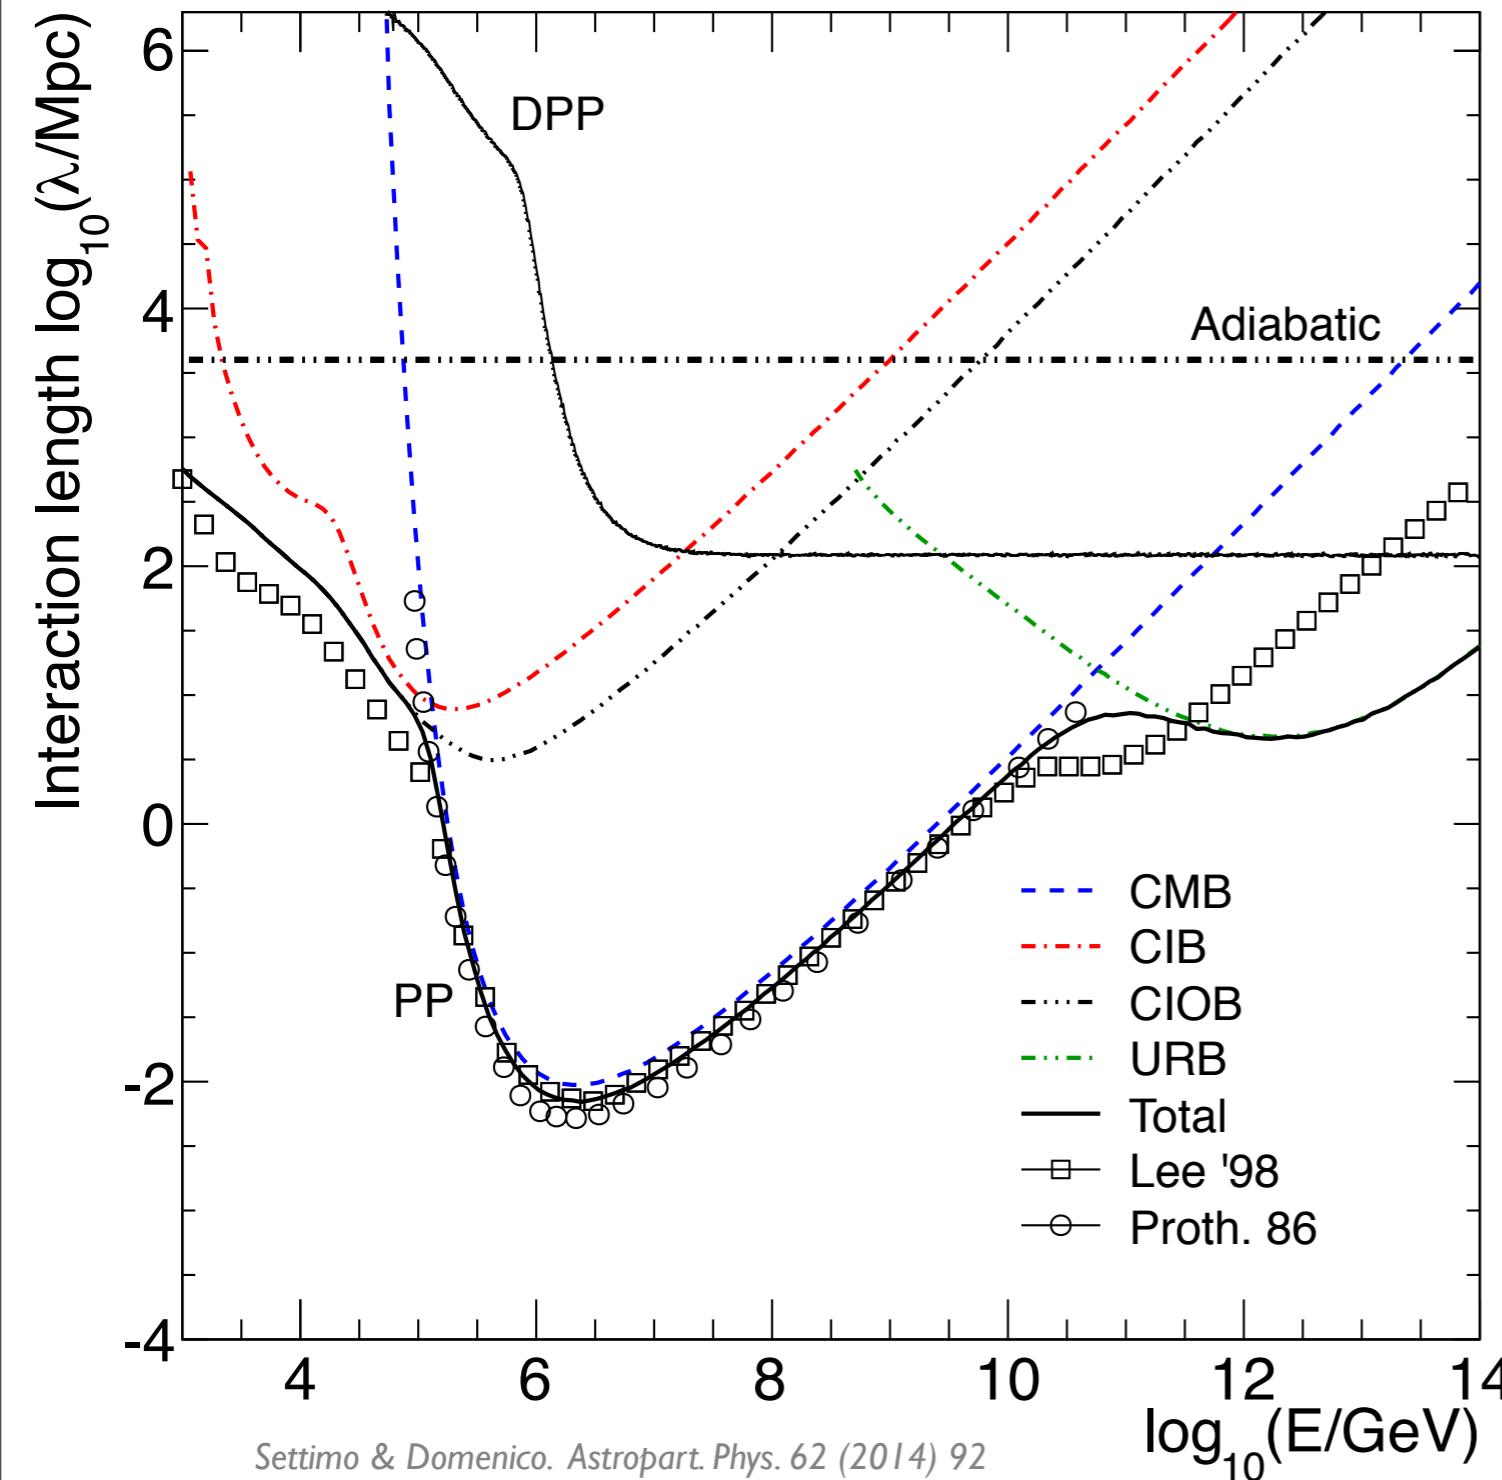

- ▶ combined spectrum-composition (1D) fits of the Auger spectrum/composition [Aloisio+ '13, Taylor '13]
- ▶ mixed composition; maximum source acceleration cutoff (no GZK)
- ▶ results suggest an extra (light) class of sources below the ankle might be needed → Auger + KASCADE-Grande data
- ▶ hard spectra “problem” [Taylor '13]: these fits seem to suggest that the sources have spectral indexes harder than expected ($\gamma \approx 1.0\text{-}1.6$); expected $\gamma \approx 2.0\text{-}2.2$ for Fermi acceleration
- ▶ magnetic horizon effects might soften the hard spectra, making it again compatible with Fermi shock acceleration [Mollerach & Roulet '13]
- ▶ magnetic horizon effects do not play a role at EeV energies in realistic extragalactic magnetic field models [RAB & Sigl '14]
- ▶ caveat I: hadronic interaction models can fail to describe interactions at the highest energies (e.g. muon problem [Auger '14])
- ▶ caveat II: source distribution, magnetic field model, nearby sources, etc
→ shape of the spectrum is sensitive to these parameters

gamma rays

interactions and energy losses

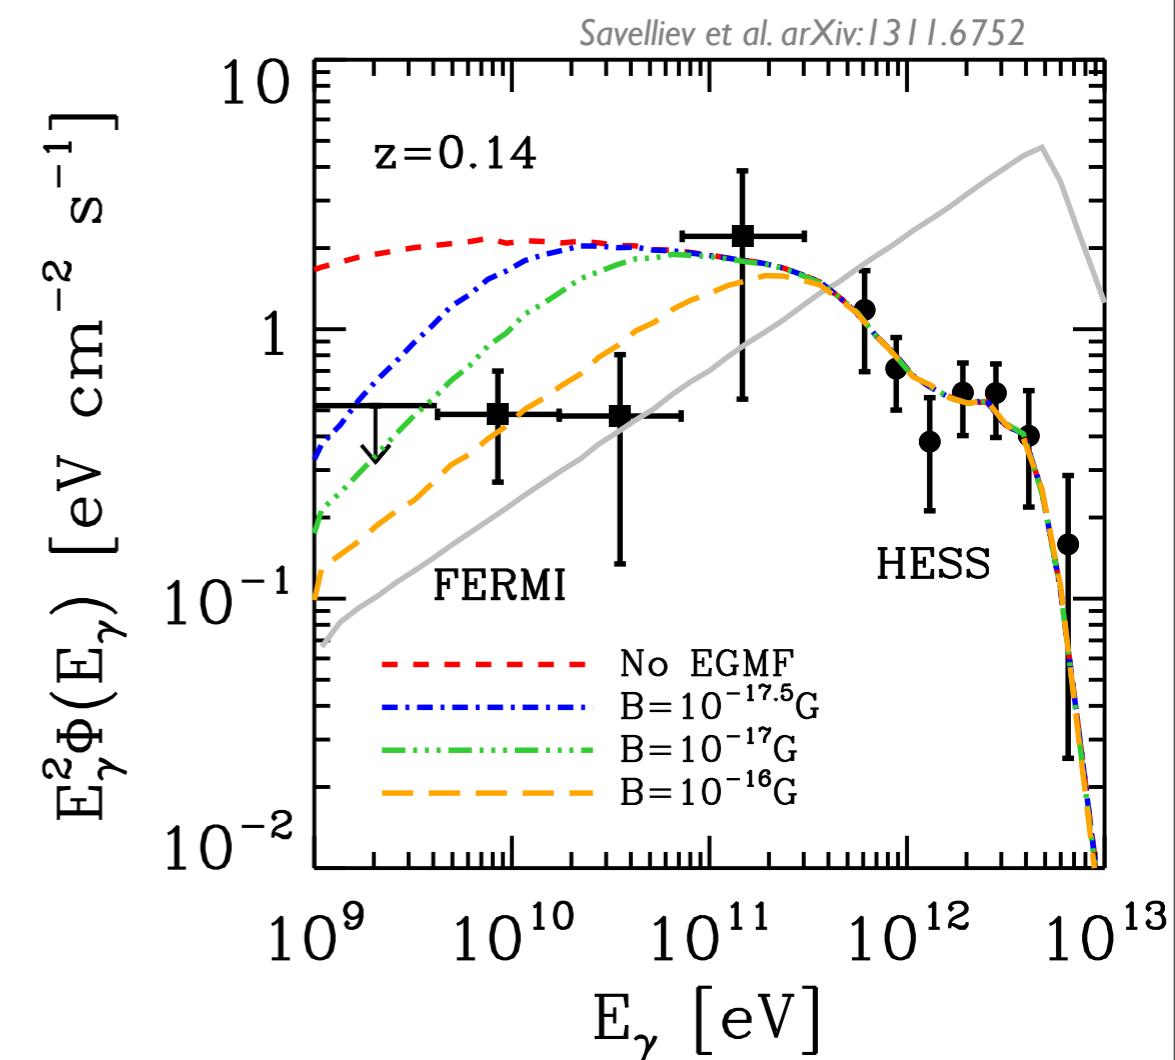

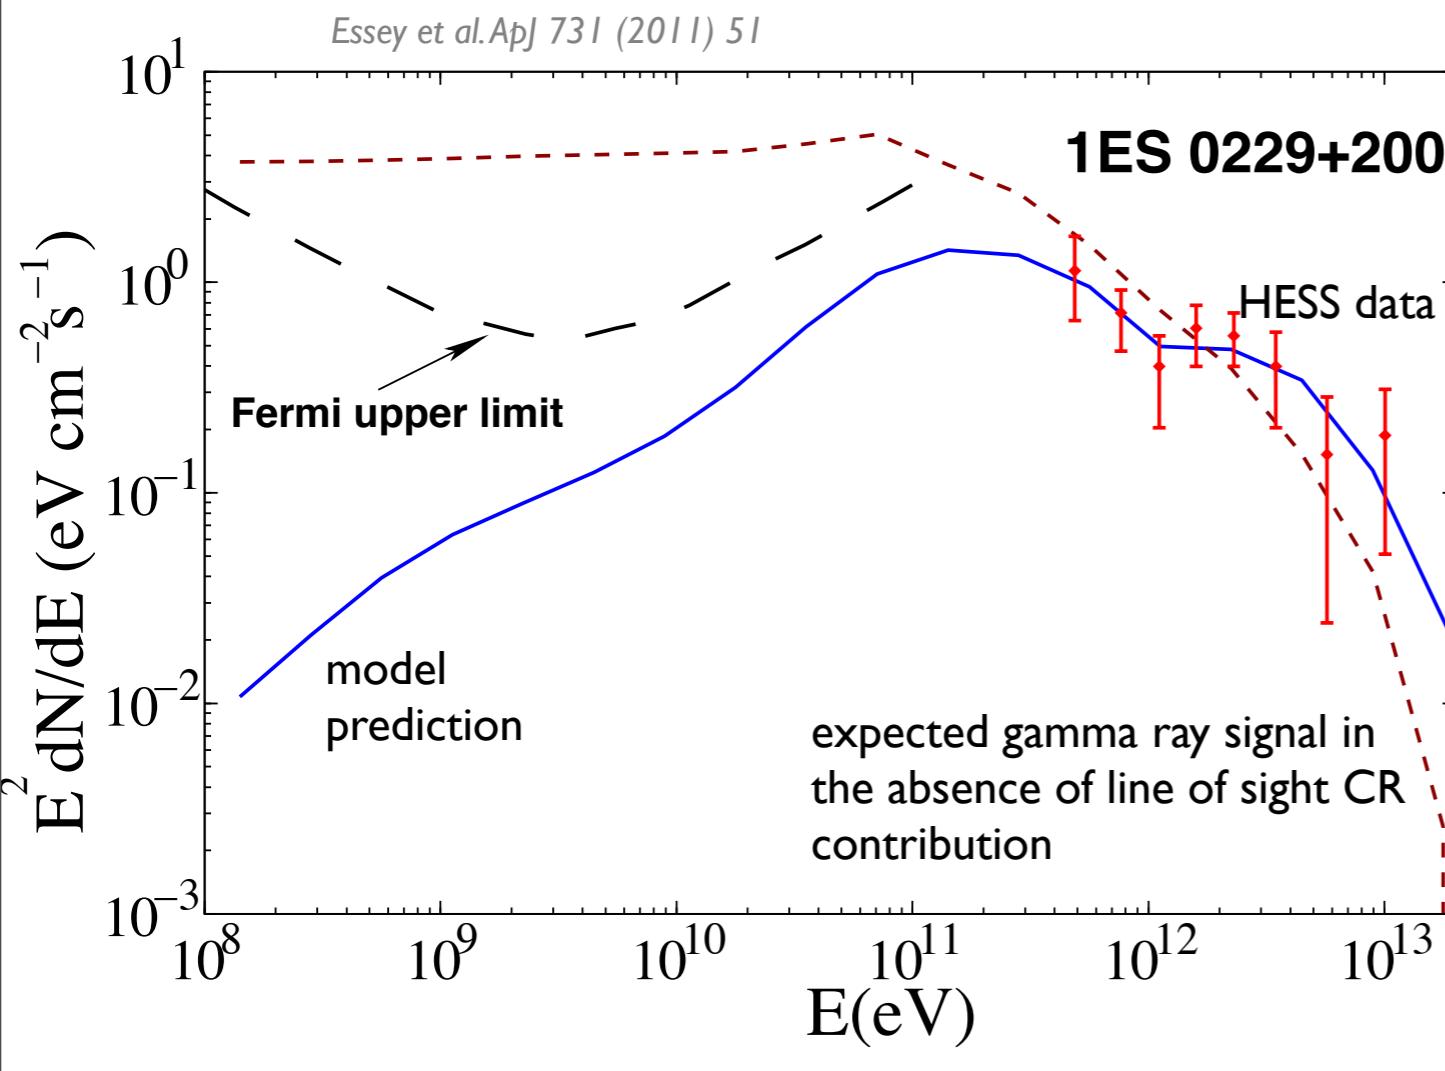

main interactions

- ▶ cosmic microwave background (CMB)
- ▶ cosmic infrared background (CIB)
- ▶ cosmic infrared and optical background (CIOB)
- ▶ universal radio background (URB)

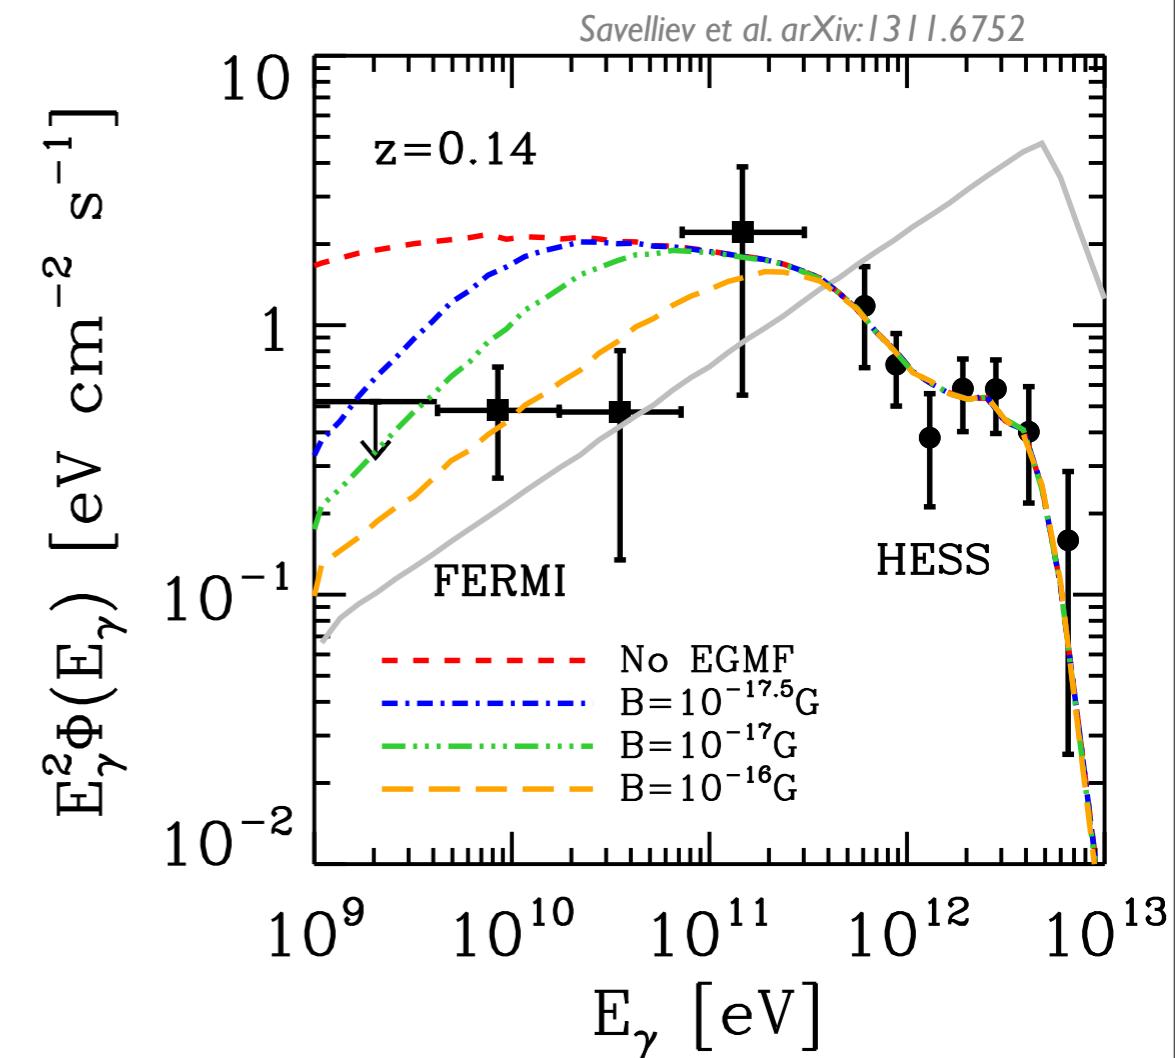

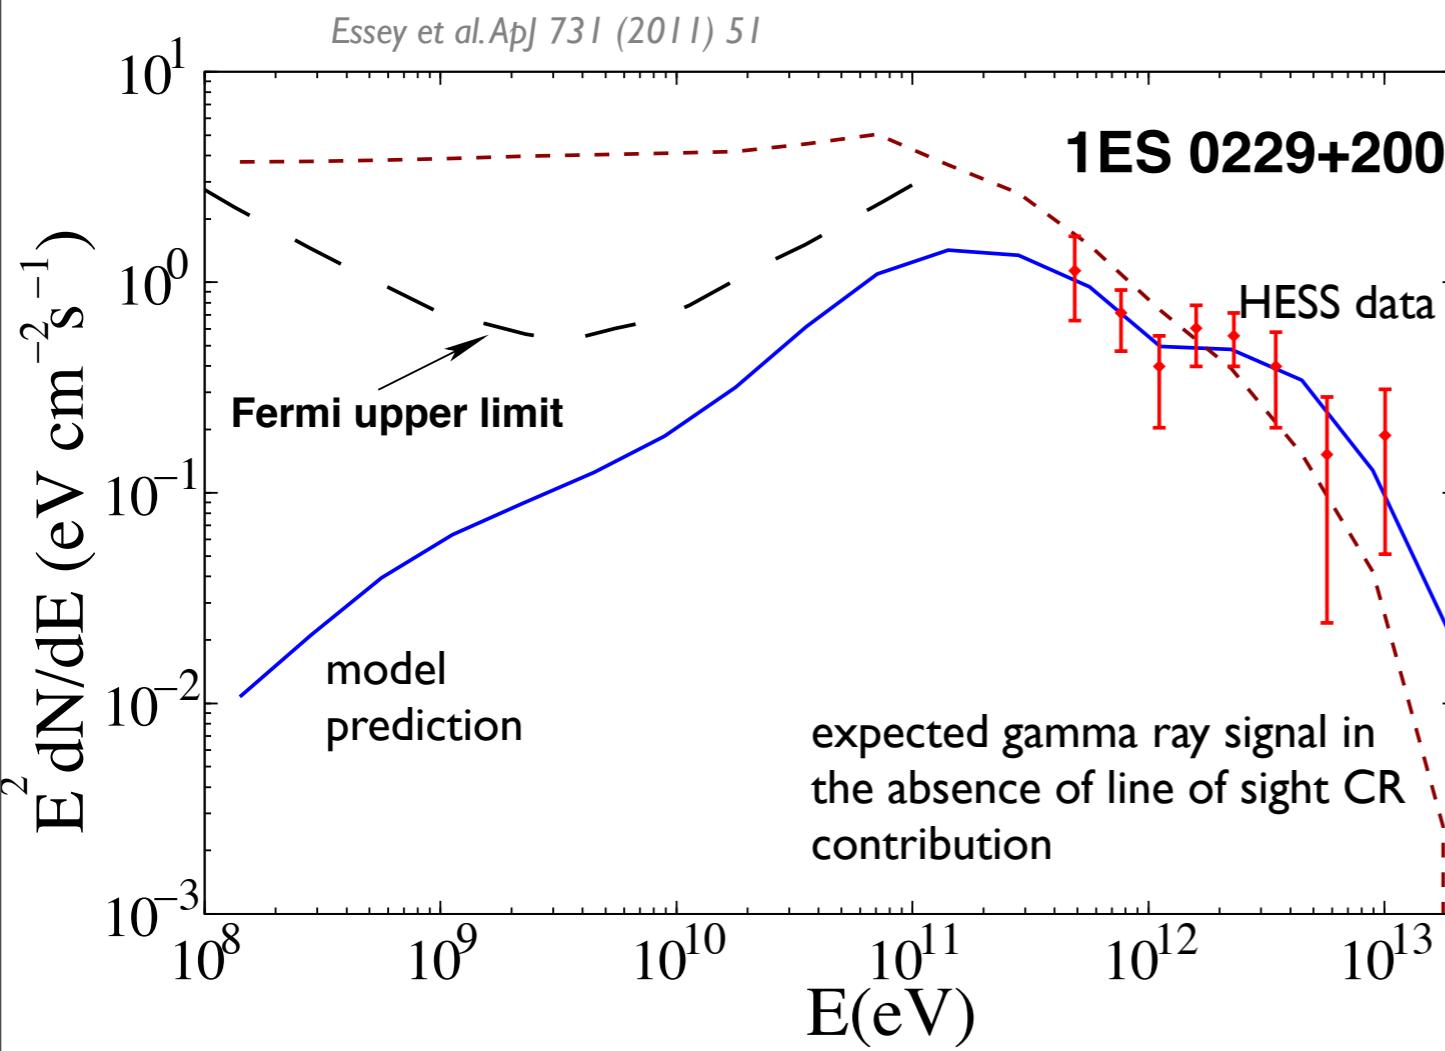

energy losses

- ▶ pair production
- ▶ double pair production
- ▶ adiabatic expansion of the universe

TeV-GeV flux “problem”

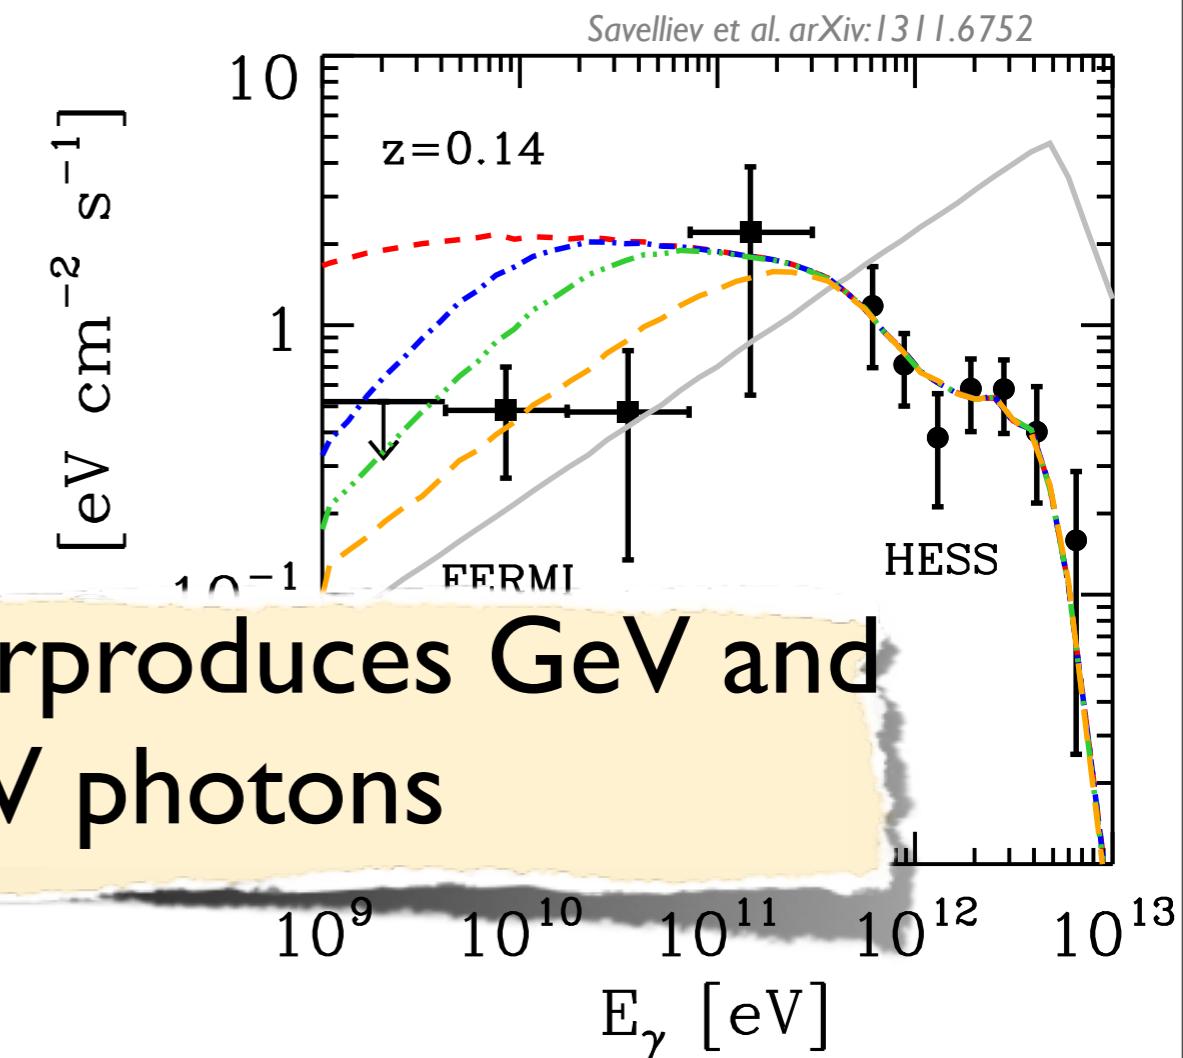

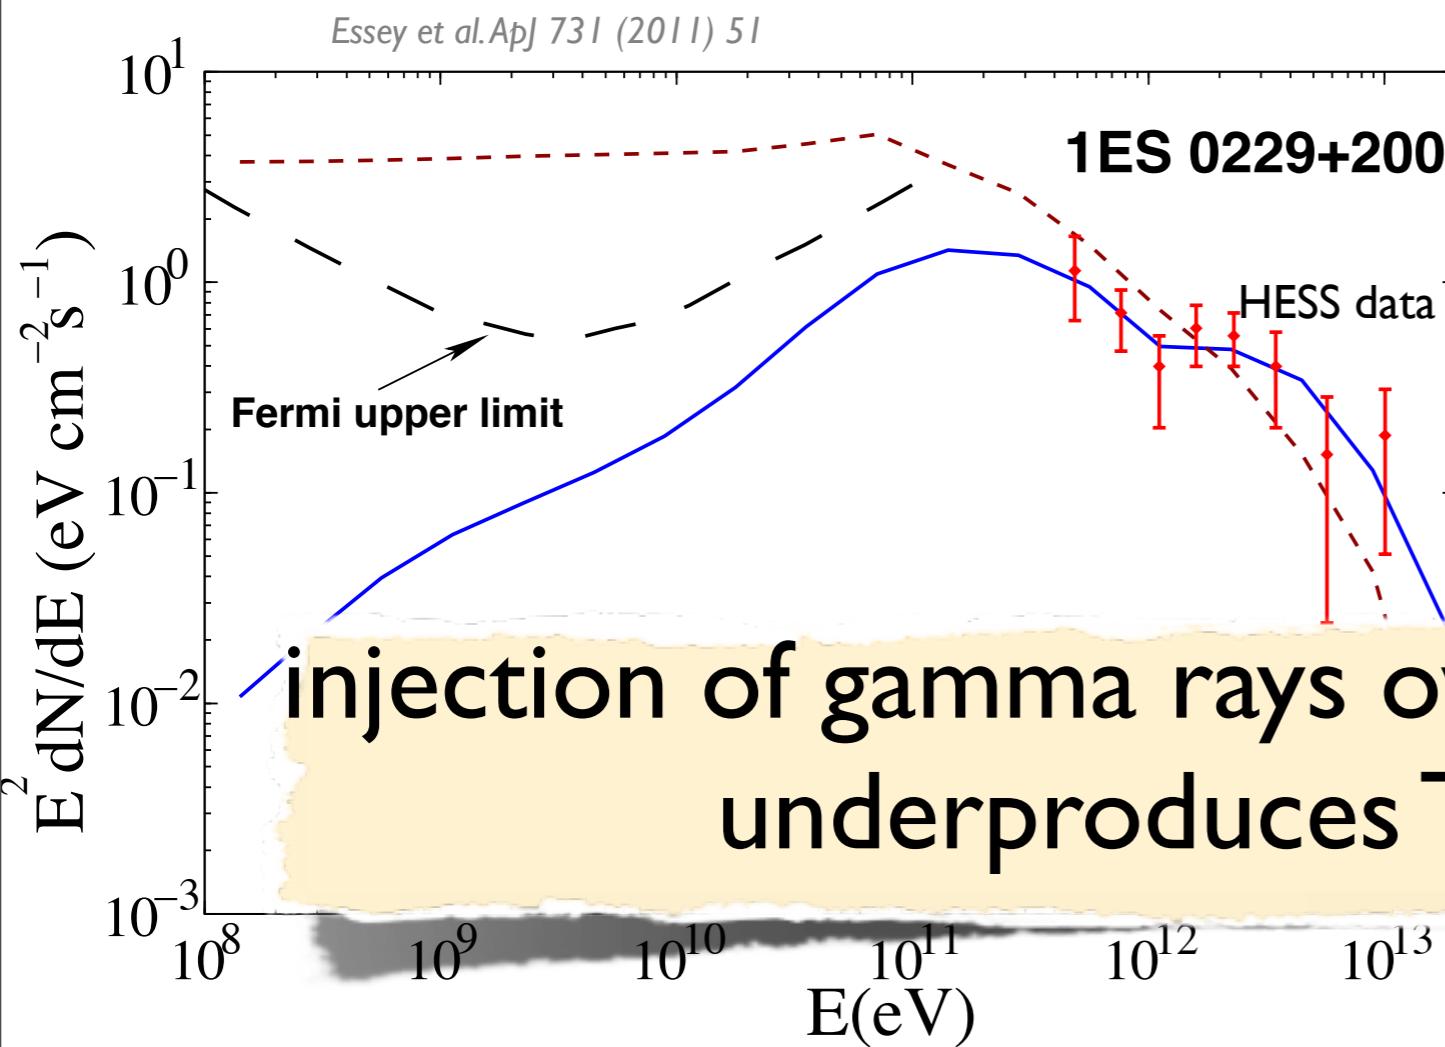

TeV-GeV flux “problem”

solutions

- ▶ $B > 10^{-17}$ G disperses the GeV cascade [Neronov & Vovk '10, Taylor+ '11]
- ▶ plasma instabilities suppresses the development of the cascades [Broderick+ '11]
- ▶ primary CRs continuously produces TeV gamma rays [Essey+ '11]
- ▶ Lorentz invariance violation [Mavromatos '10]
- ▶ gamma ray mixing with ALPs or hidden photons [Horns+ '12]

TeV-GeV flux “problem”

injection of gamma rays overproduces GeV and underproduces TeV photons

solutions

- ▶ $B > 10^{-17}$ G disperses the GeV cascade [Neronov & Vovk '10, Taylor+ '11]
- ▶ plasma instabilities suppresses the development of the cascades [Broderick+ '11]
- ▶ primary CRs continuously produces TeV gamma rays [Essey+ '11]
- ▶ Lorentz invariance violation [Mavromatos '10]
- ▶ gamma ray mixing with ALPs or hidden photons [Horns+ '12]

electromagnetic cascades

- ▶ time delayed photons from primary gamma rays
[Plaga '94, Murase+ '08]
- ▶ gamma rays emitted by blazars
- ▶ gamma rays produce e^+e^- pairs \rightarrow scatter background photons via inverse Compton
- ▶ point-like sources will appear extended [Plaga '94]
- ▶ cascades \rightarrow lower limits on the extragalactic magnetic field [Neronov & Semikoz '09]
- ▶ flux suppression at $E \sim \text{GeV}$ [Neronov & Semikoz '09, Vovk+ '12]
- ▶ controversial issue: plasma instabilities may play a role and suppress the development of the cascades [Saveliev+ '13]
- ▶ can be induced by gamma rays and high energy cosmic rays

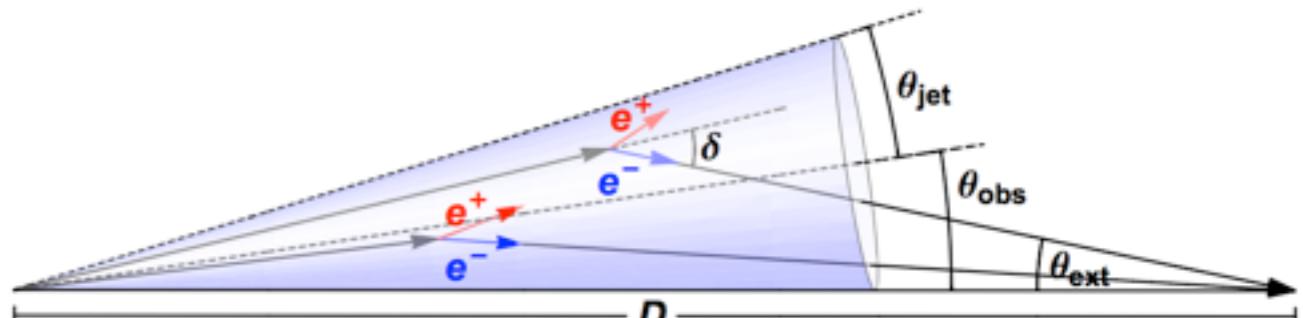

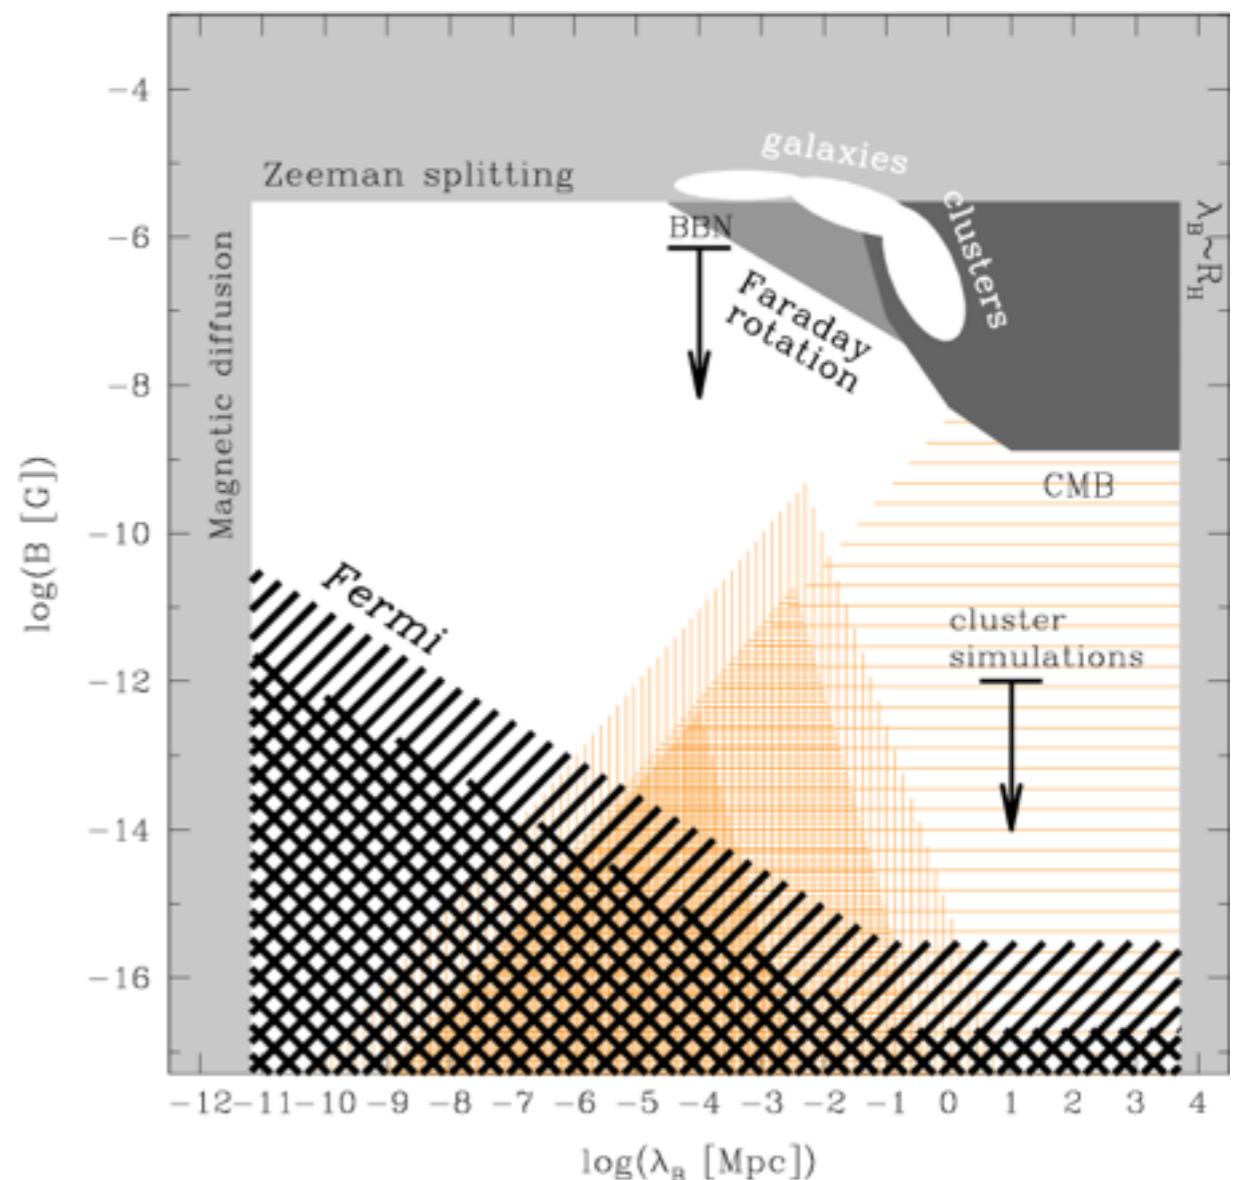

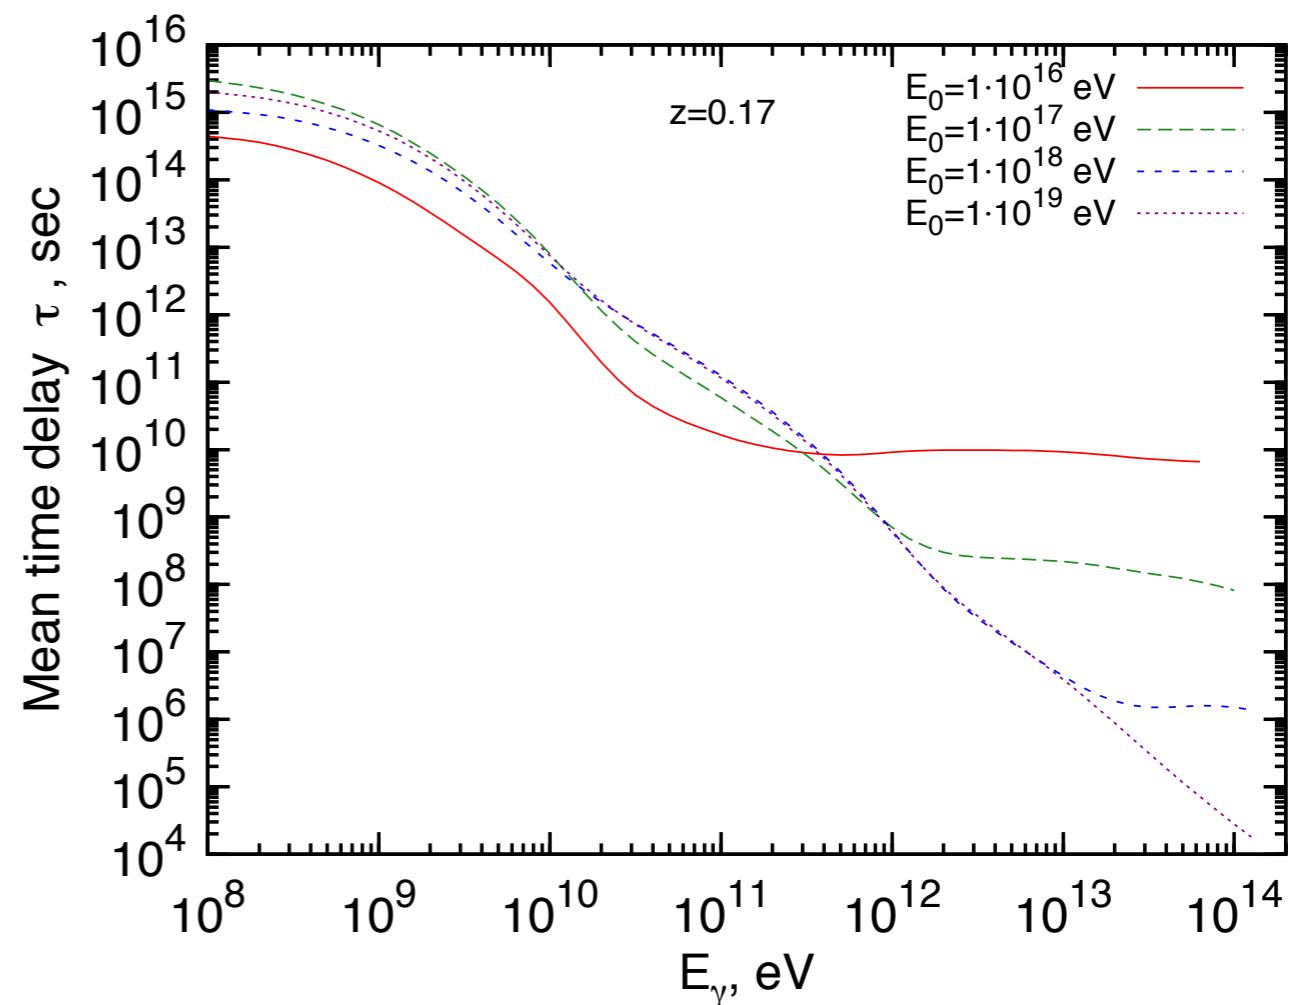

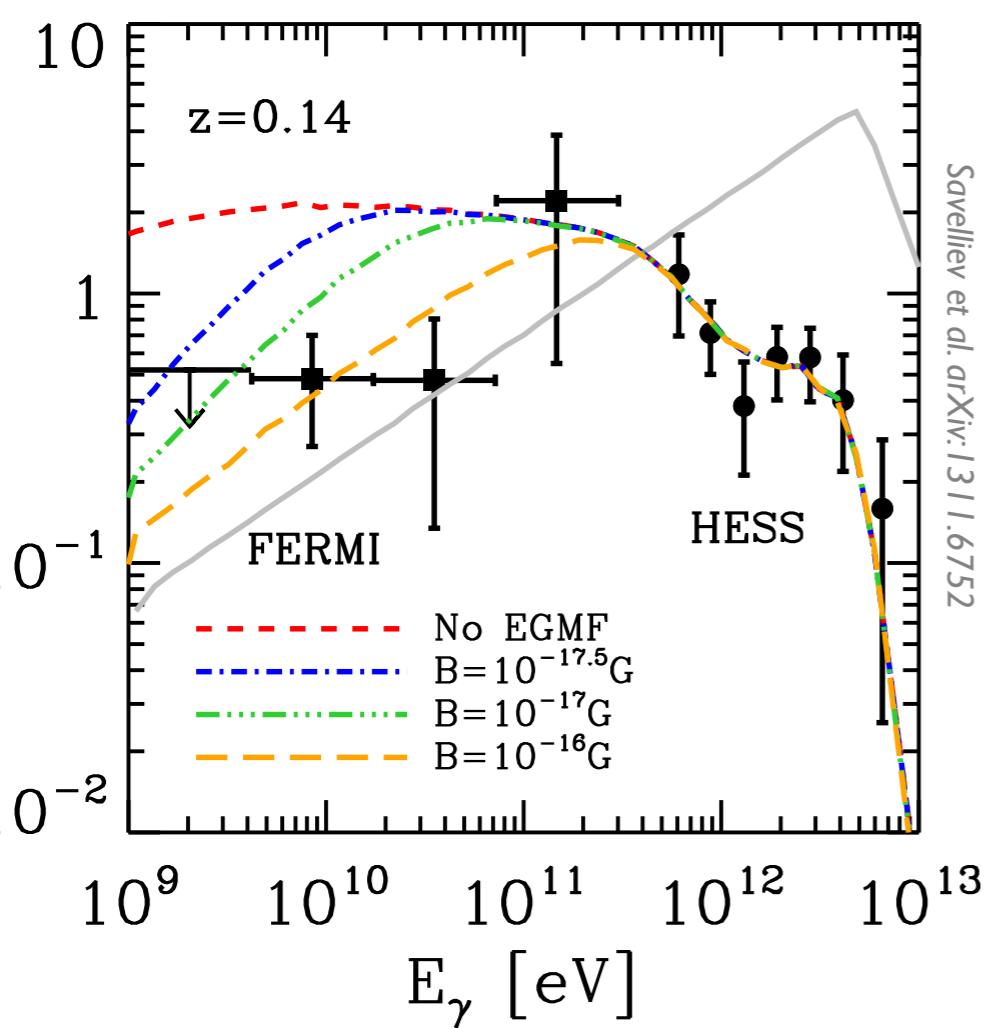

Figure by Andrey Saveliev

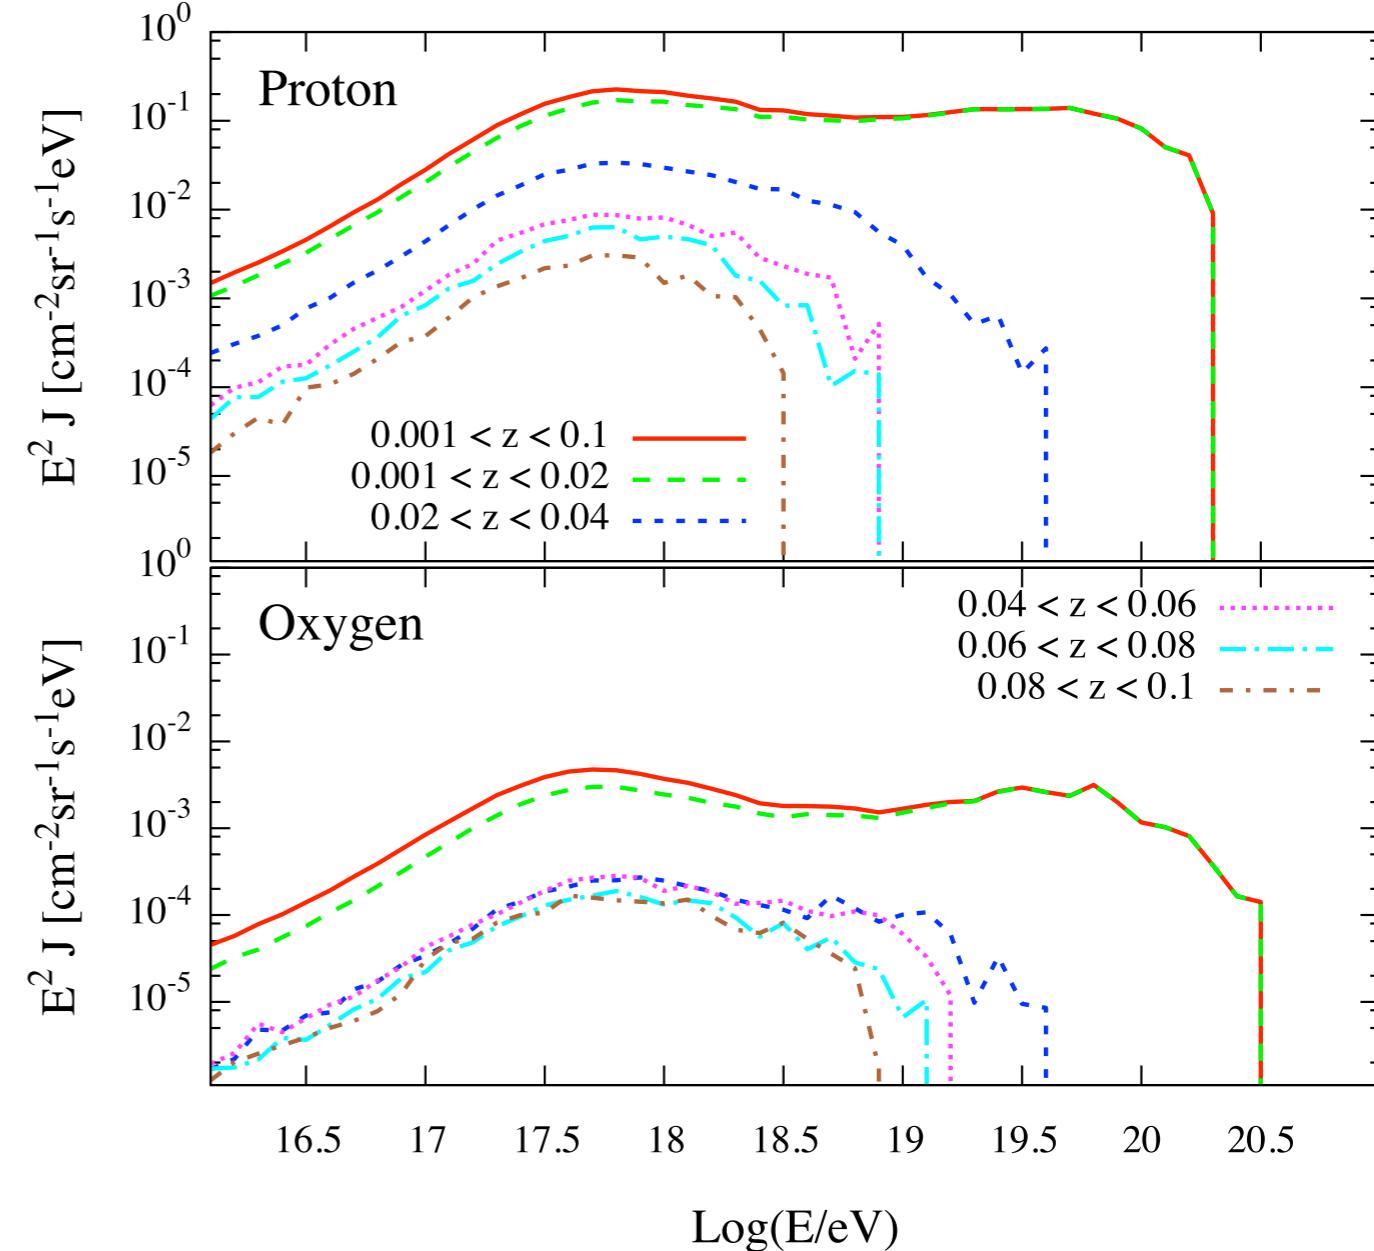

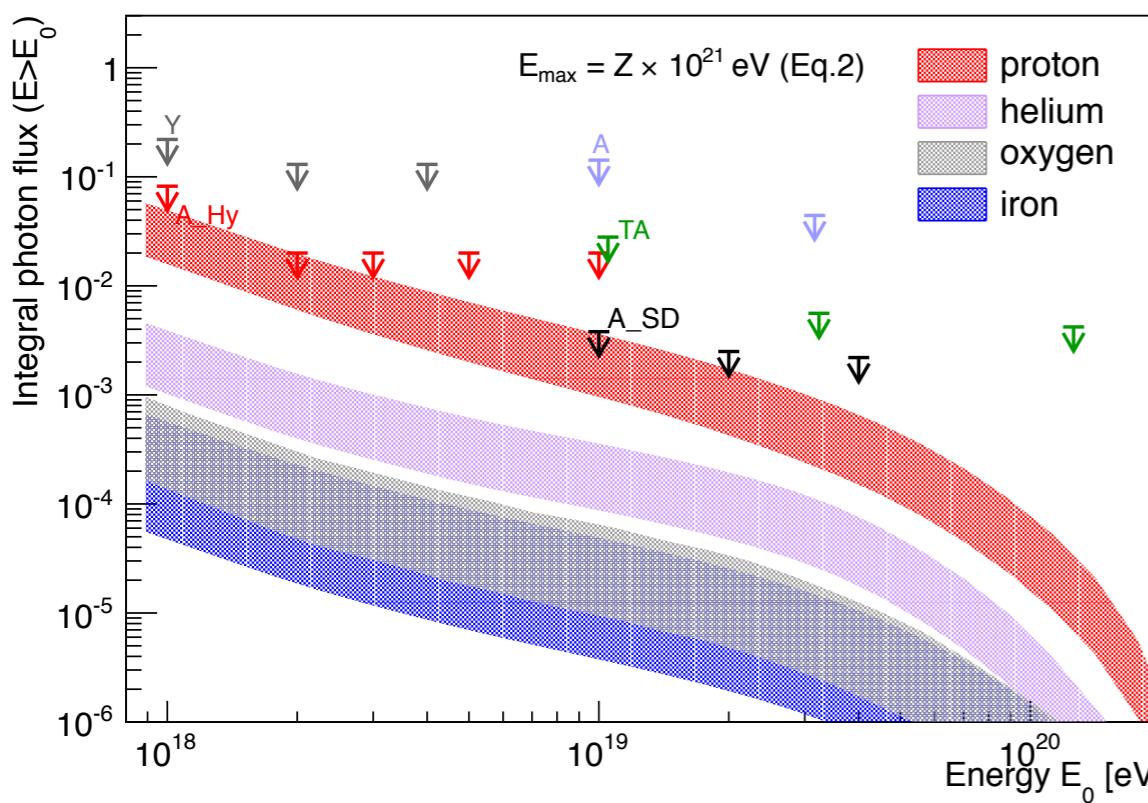

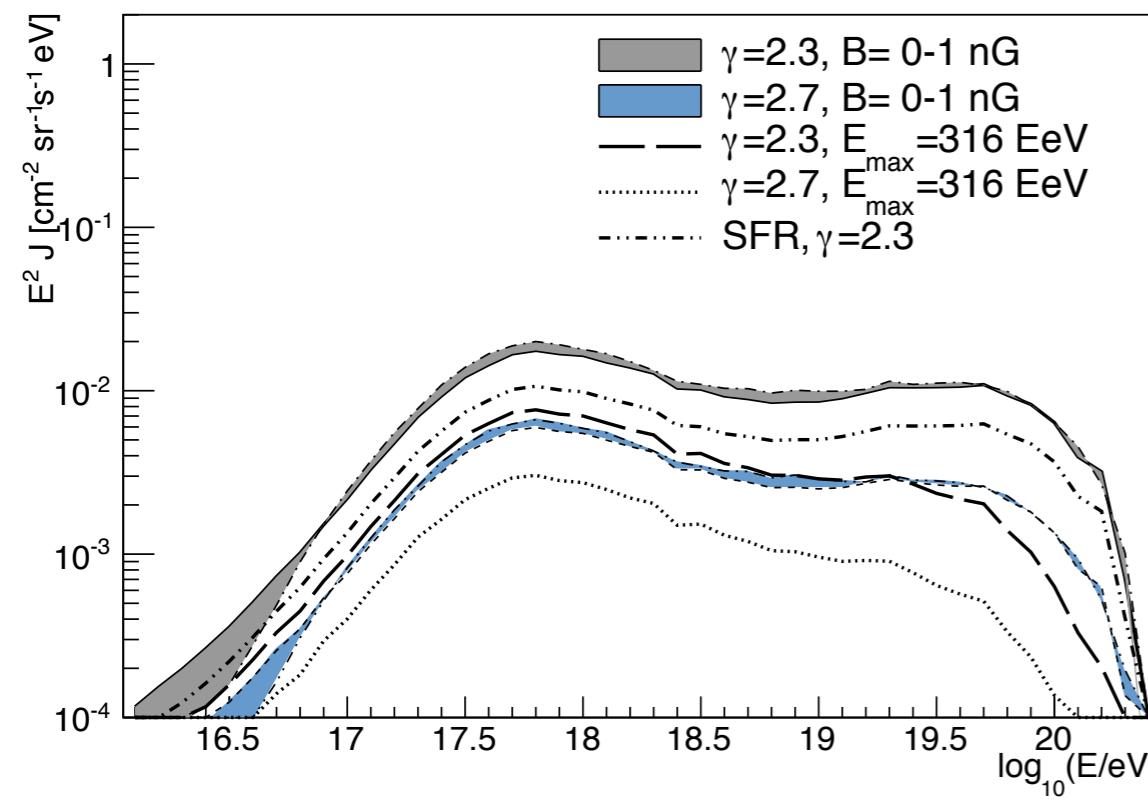

electromagnetic cascades

A. Kusenku. Mod. Phys. Lett. A 28 (2013) 1340001

ultra-high energy photons

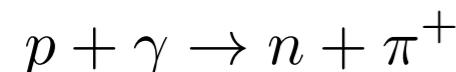

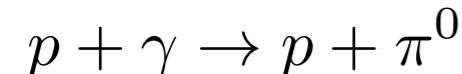

results obtained with the EleCa code
[Settimi & De Domenico '14]

A photograph of the Aurora Borealis (Northern Lights) in a dark, rural setting. The sky is filled with bright, swirling green and yellow light streaks against a dark background. A small, dark wooden fence or gate is visible in the lower center foreground, and a few distant lights are visible in the distance.

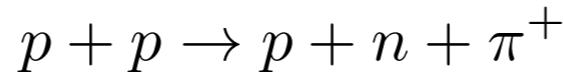

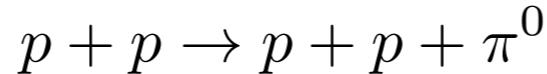

neutrinos

pion production and neutrinos

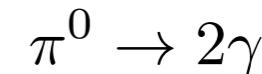

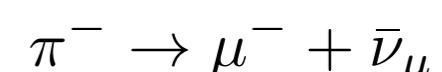

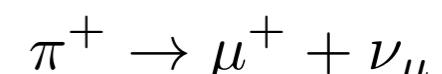

proton-gamma

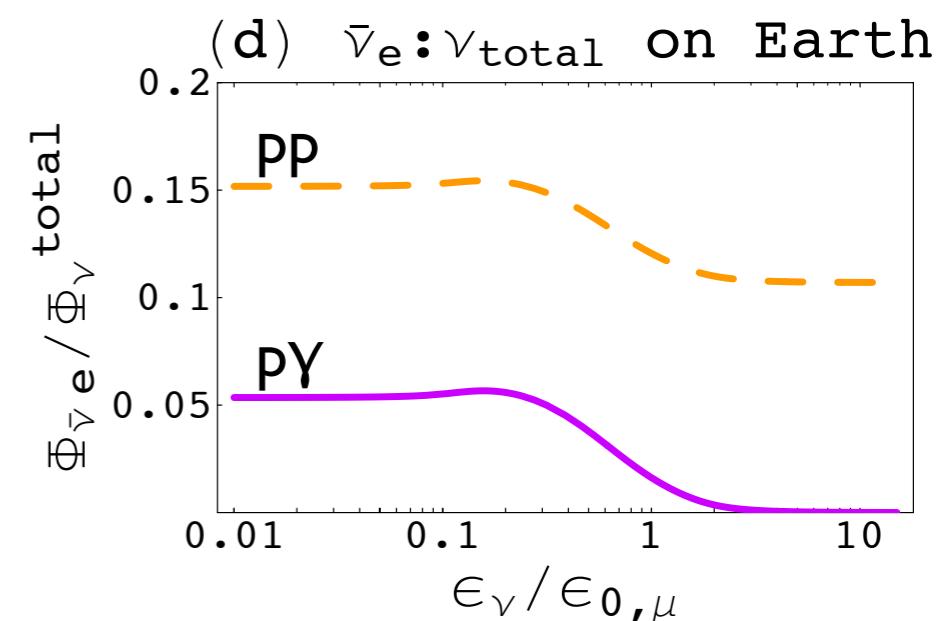

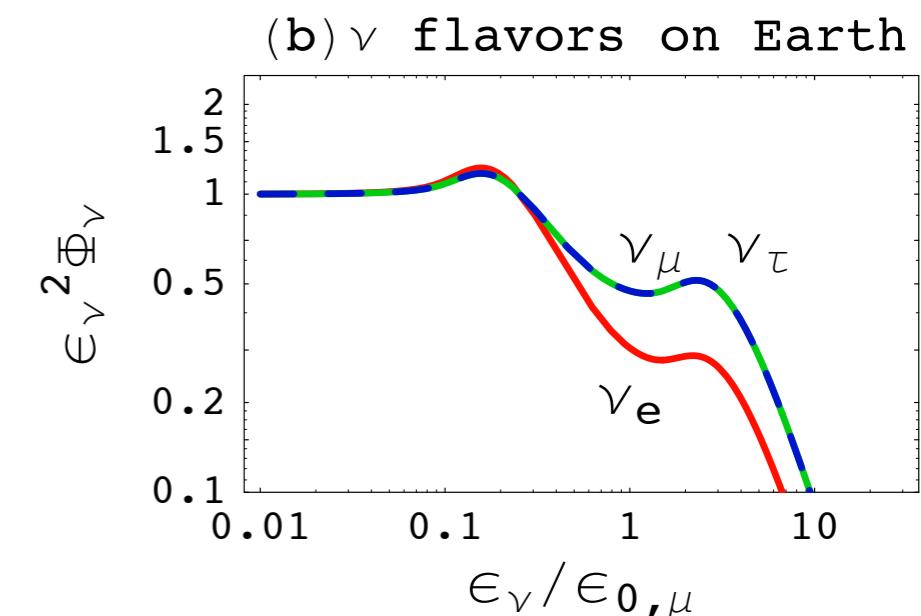

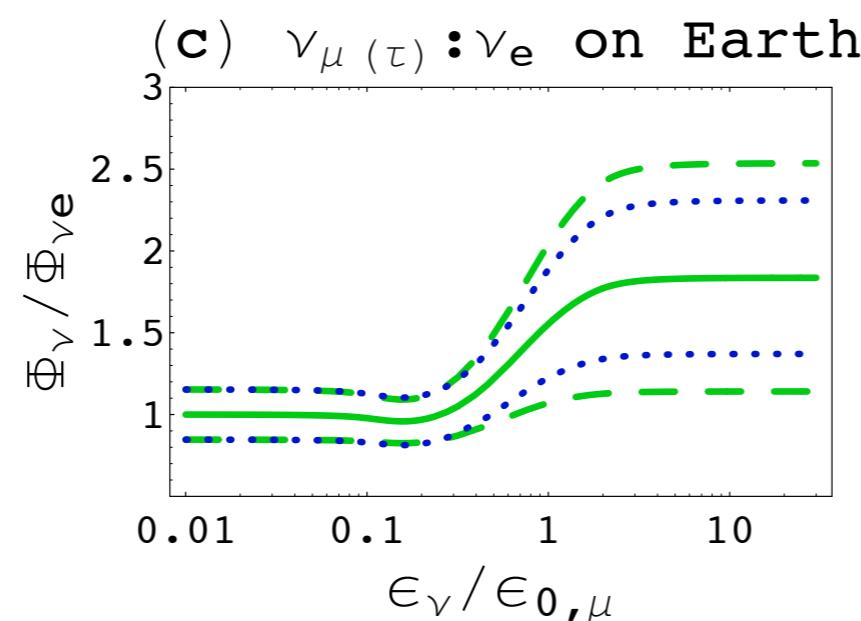

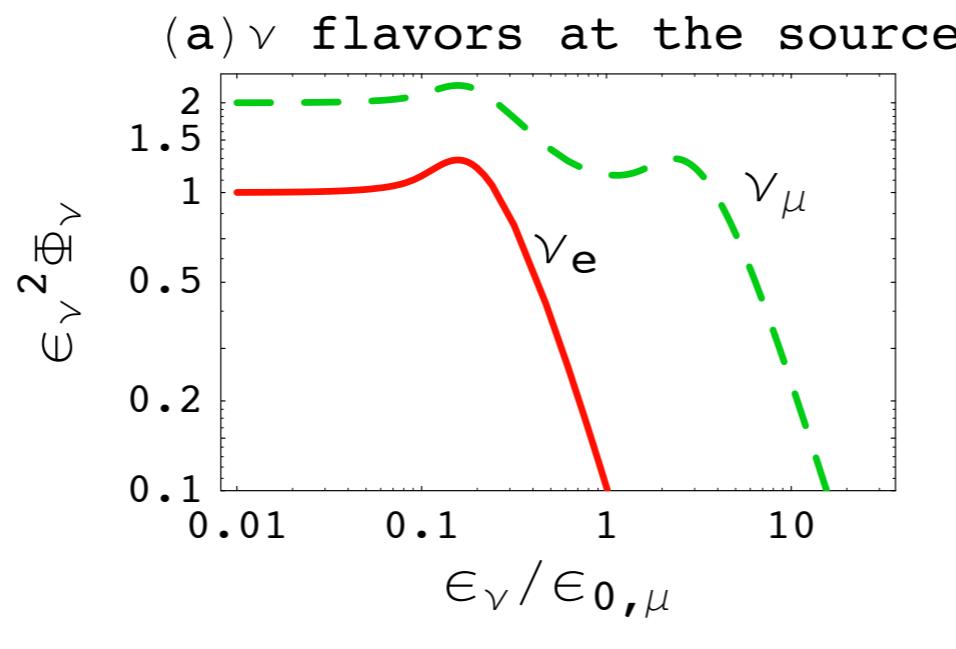

proton-proton

pion decay

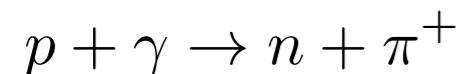

- injection of pions with energy E_π
- energy loss: $dE/dt \sim E_\pi^2$
- $E_{0,\mu}$ (energy at which decay equals energy losses)

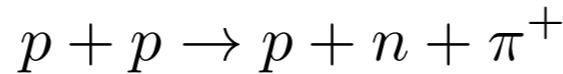

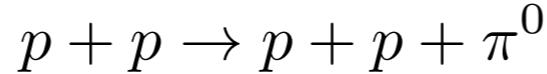

pion production and neutrinos

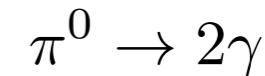

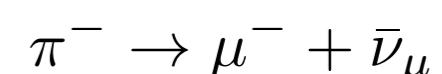

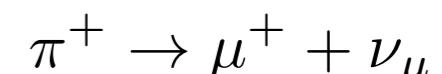

proton-gamma

proton-proton

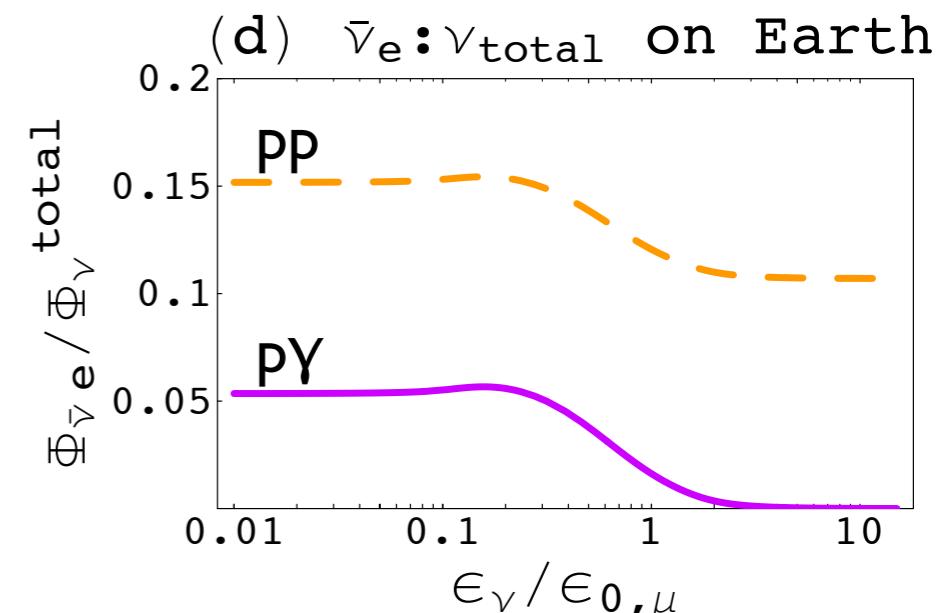

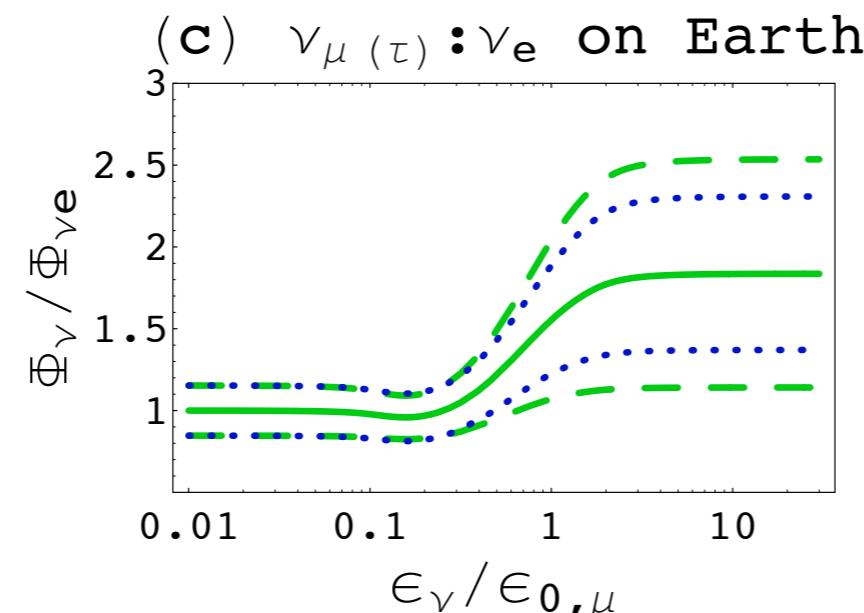

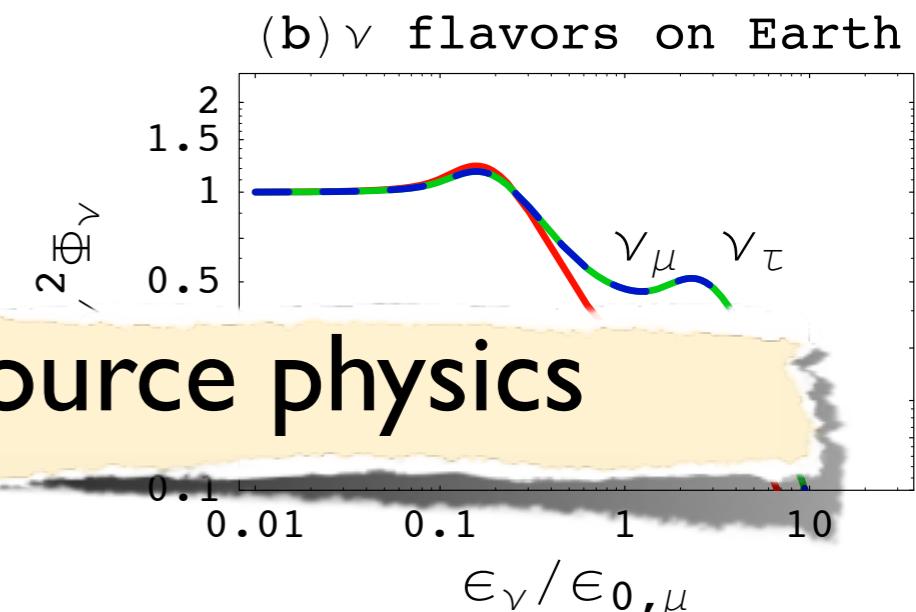

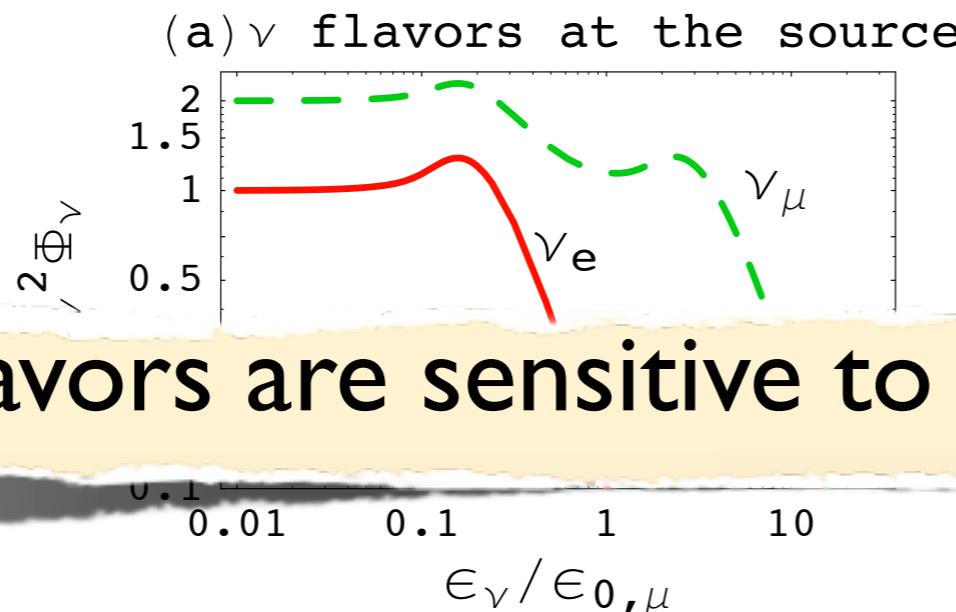

pion decay

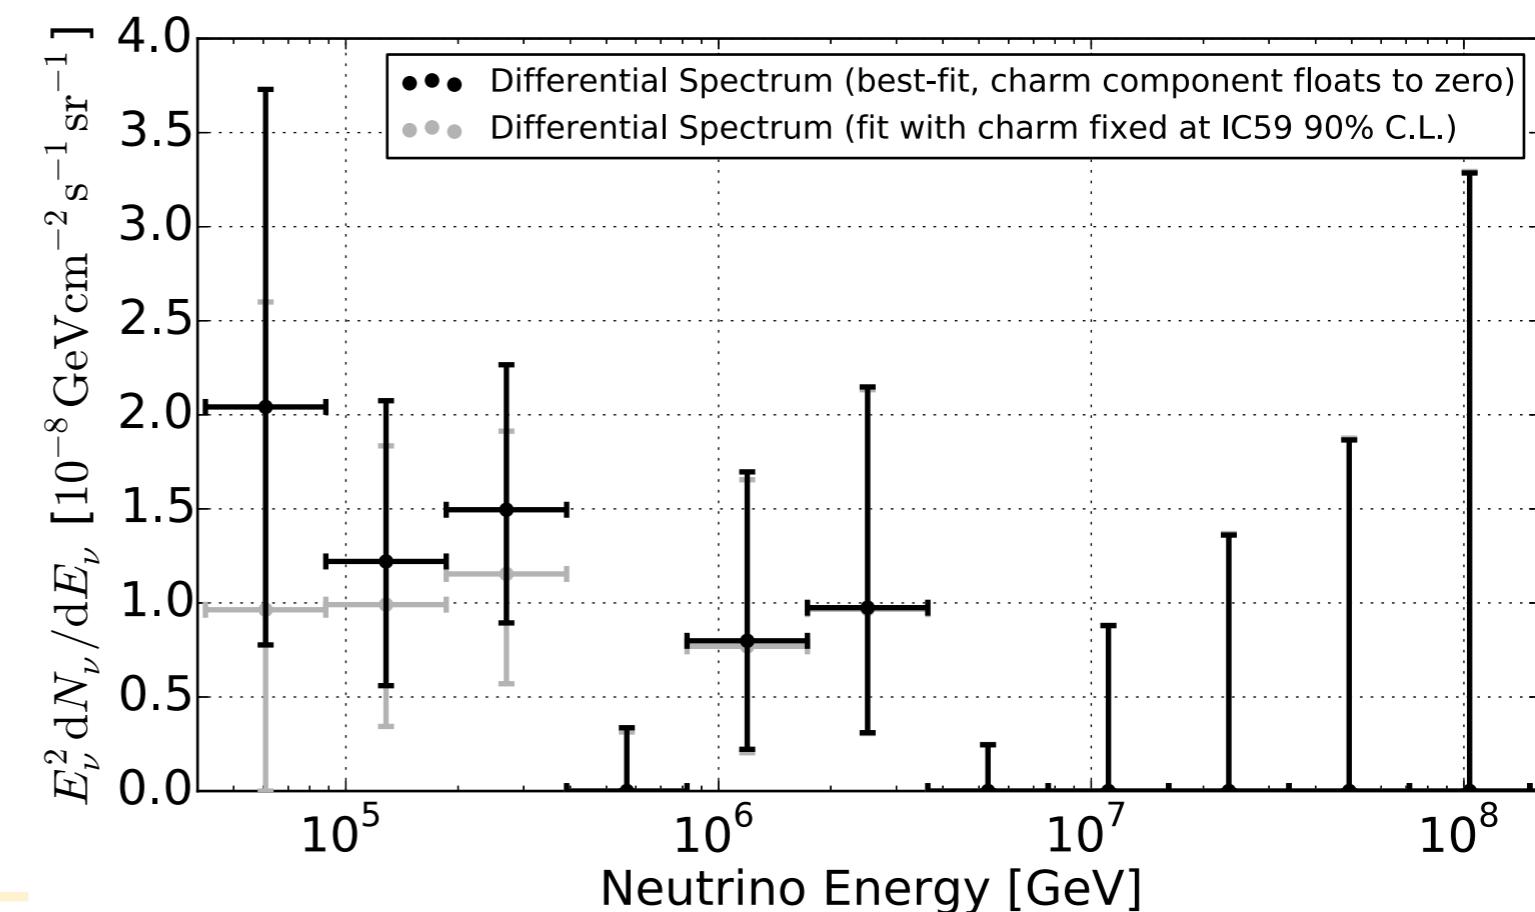

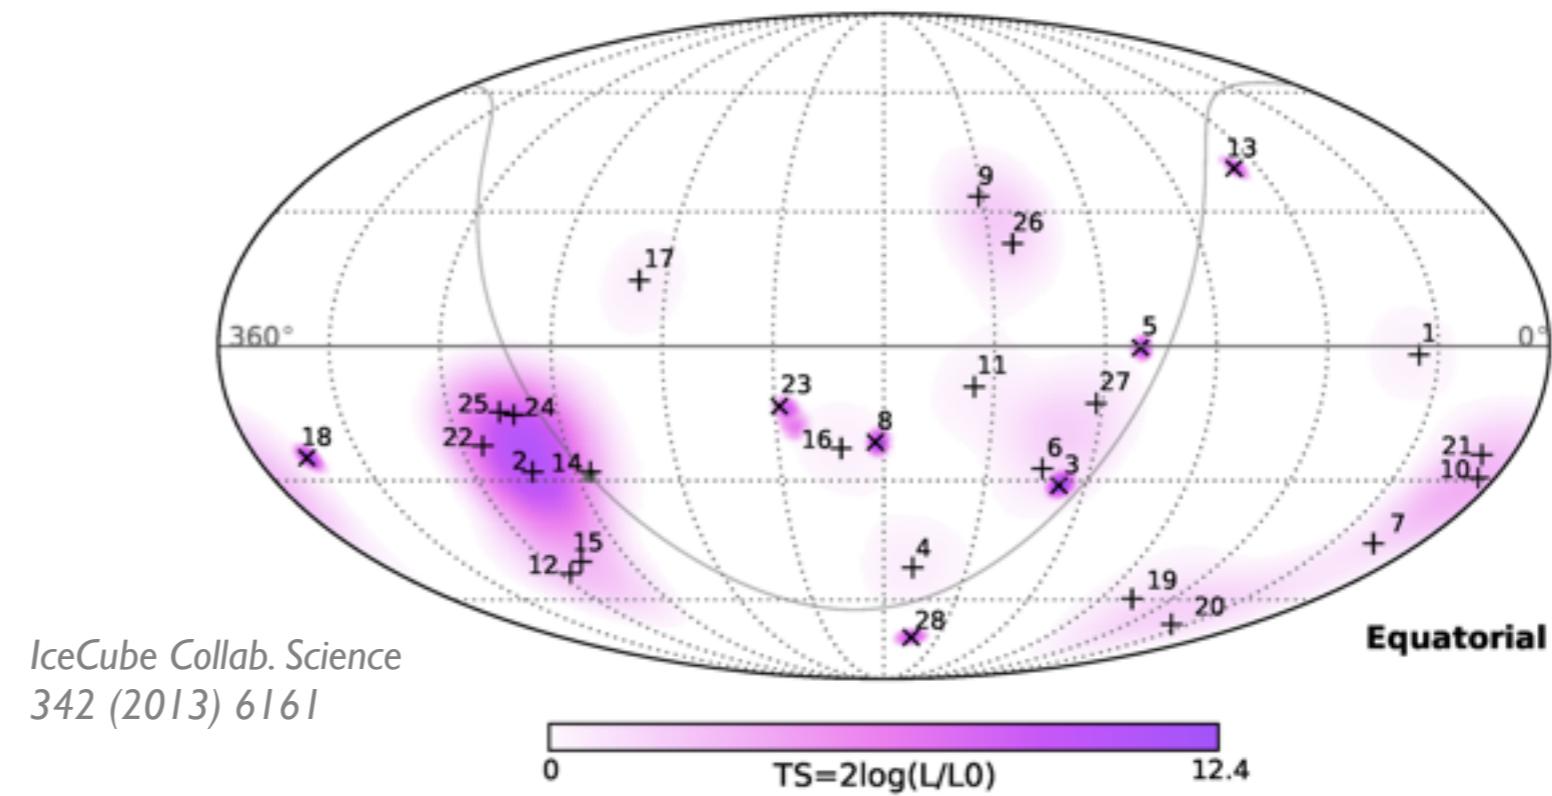

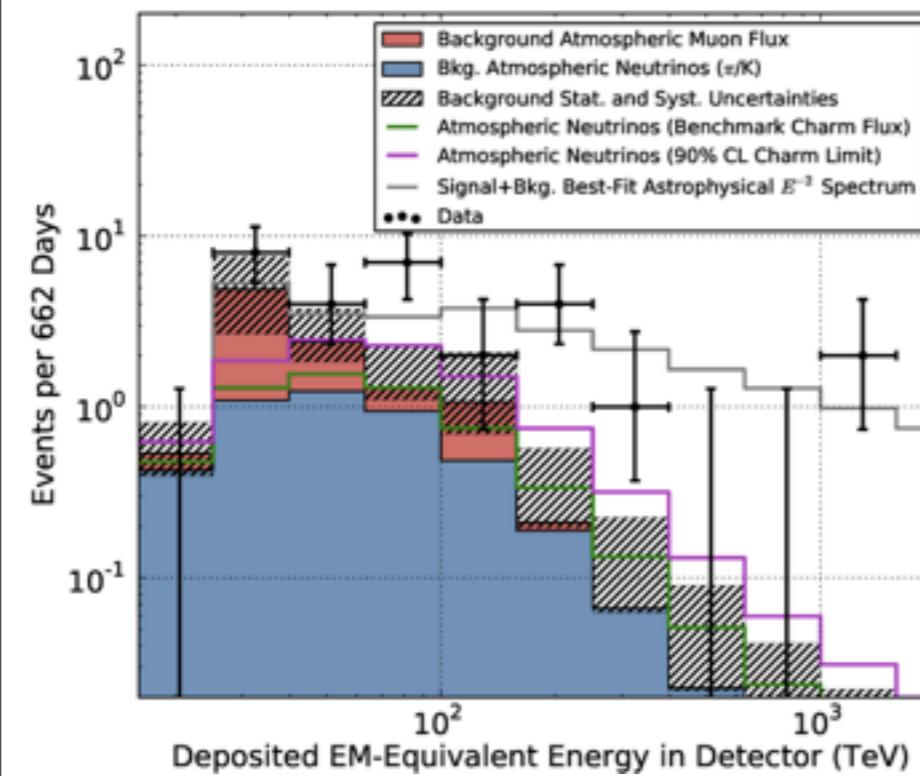

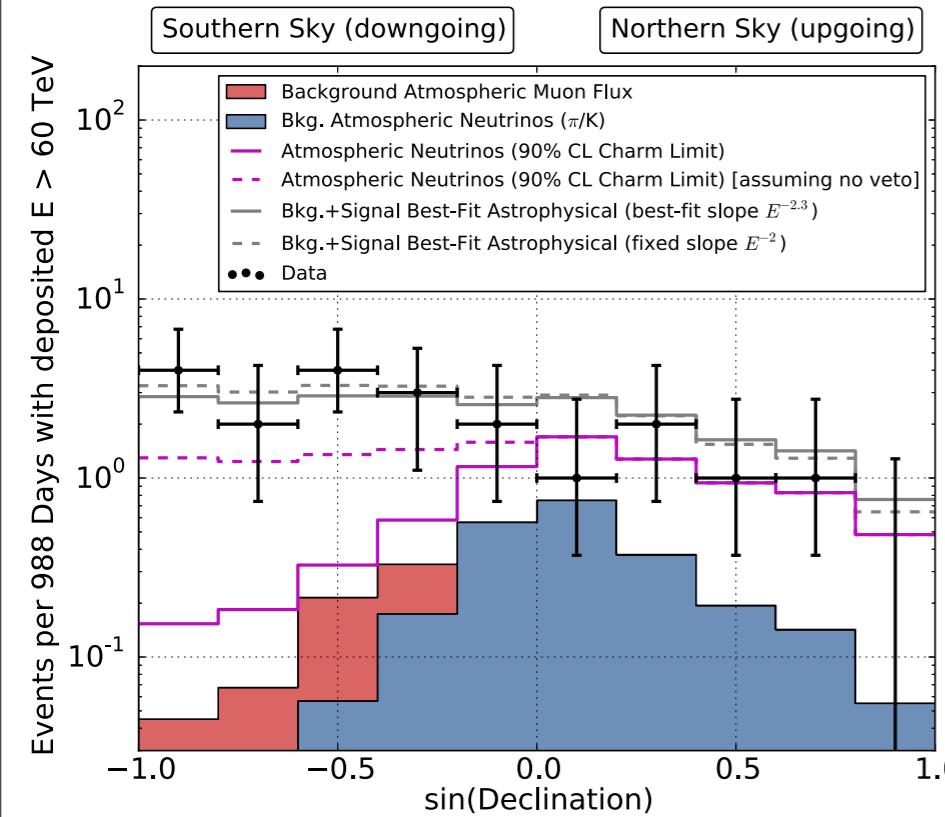

- ▶ injection of pions with energy E_π
- ▶ energy loss: define $E_{0,\mu}$ (energy at which decay equals energy losses)

flavors are sensitive to source physics

Kashti & Waxman. PRL
95 (2005) 111801

high energy neutrinos

origin of high energy neutrinos

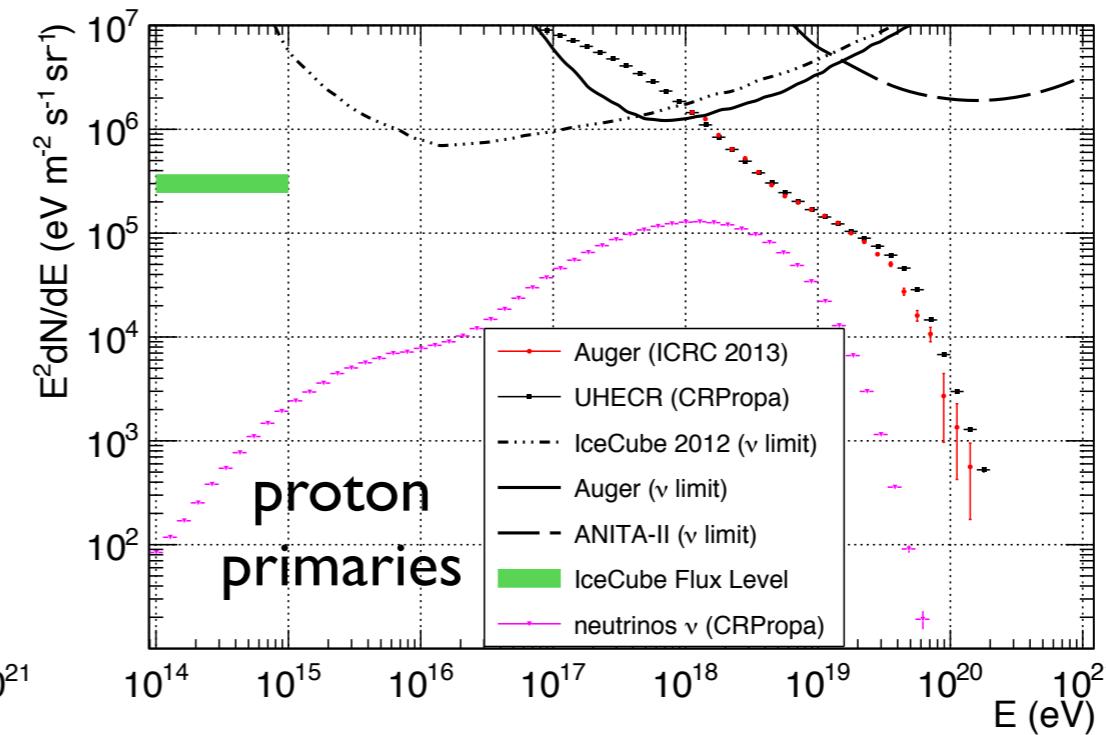

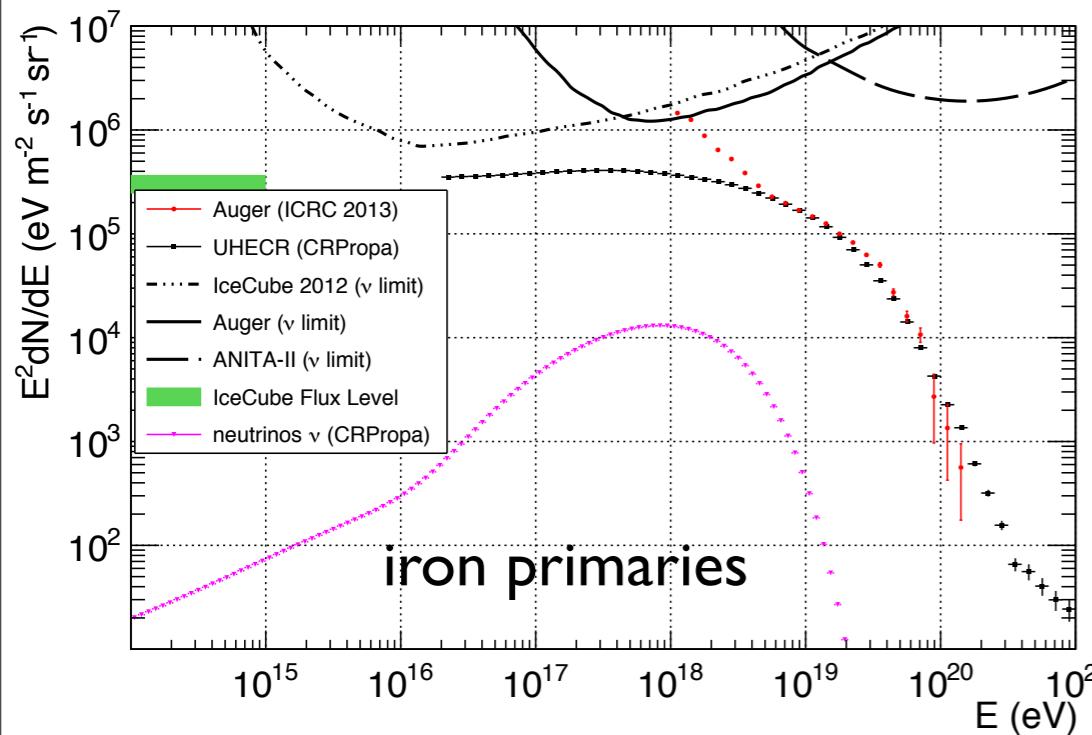

galactic sources

- ▶ hypernovae [Fox+ '13, Ahlers & Murase '14]
- ▶ diffusive galactic emission [Ahlers & Murase '14, Neronov+ '14]
- ▶ unidentified galactic gamma ray sources [Fox+ '13]

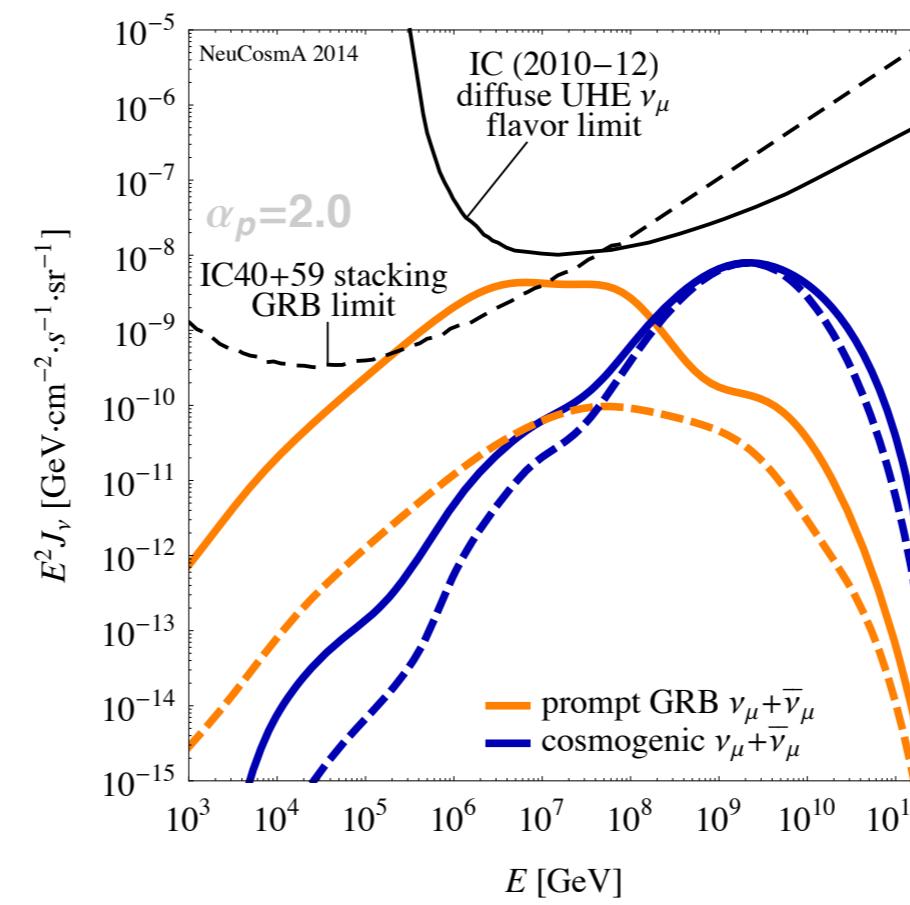

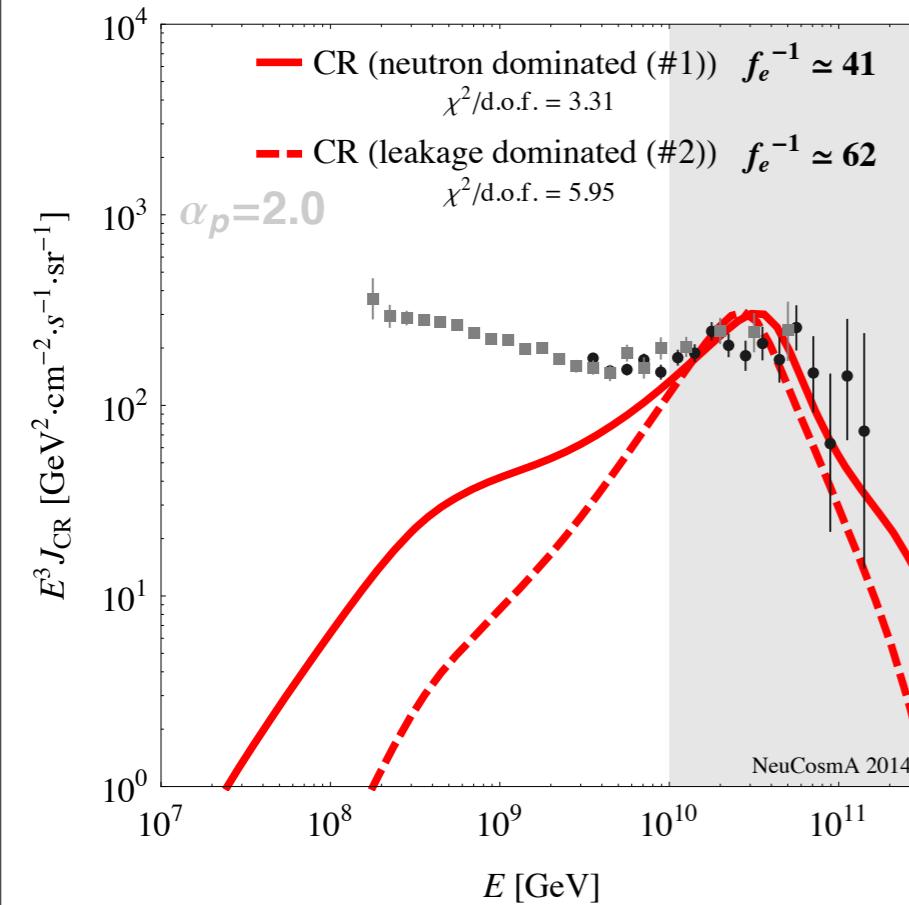

extragalactic sources

- ▶ galaxy clusters [Berezinsky+ '97, Murase+ '13]
- ▶ starburst galaxies [Loeb & Waxman '06, Murase+ '13]
- ▶ AGNs [Stecker+ '91]
- ▶ GRBs [Murase & Ioka '13]
- ▶ extragalactic hypernovae [Liu+ '14]

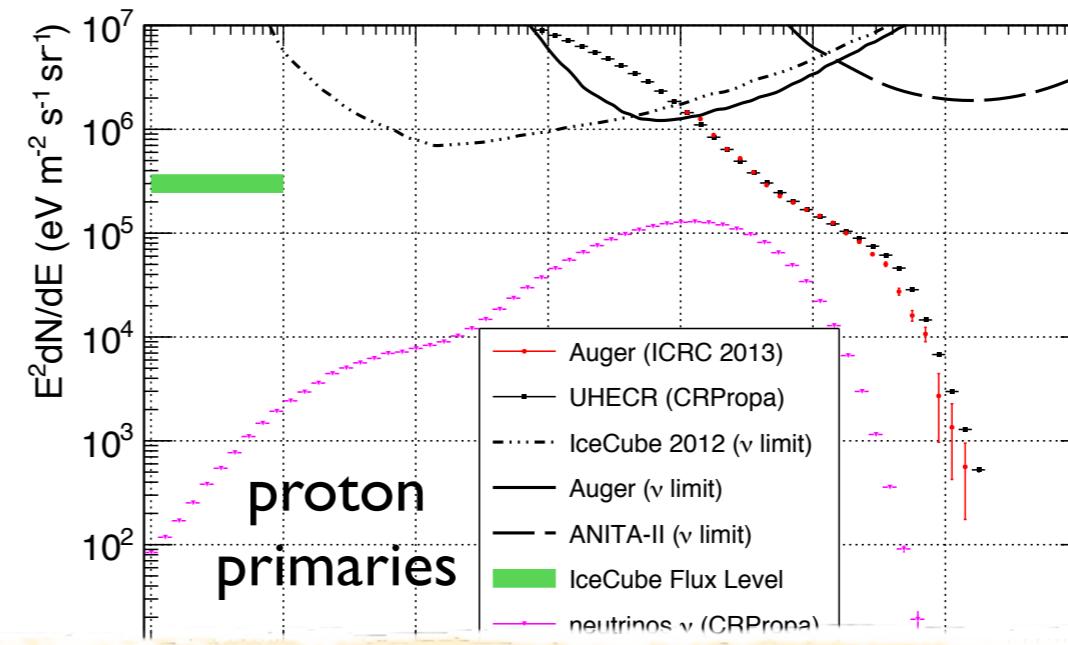

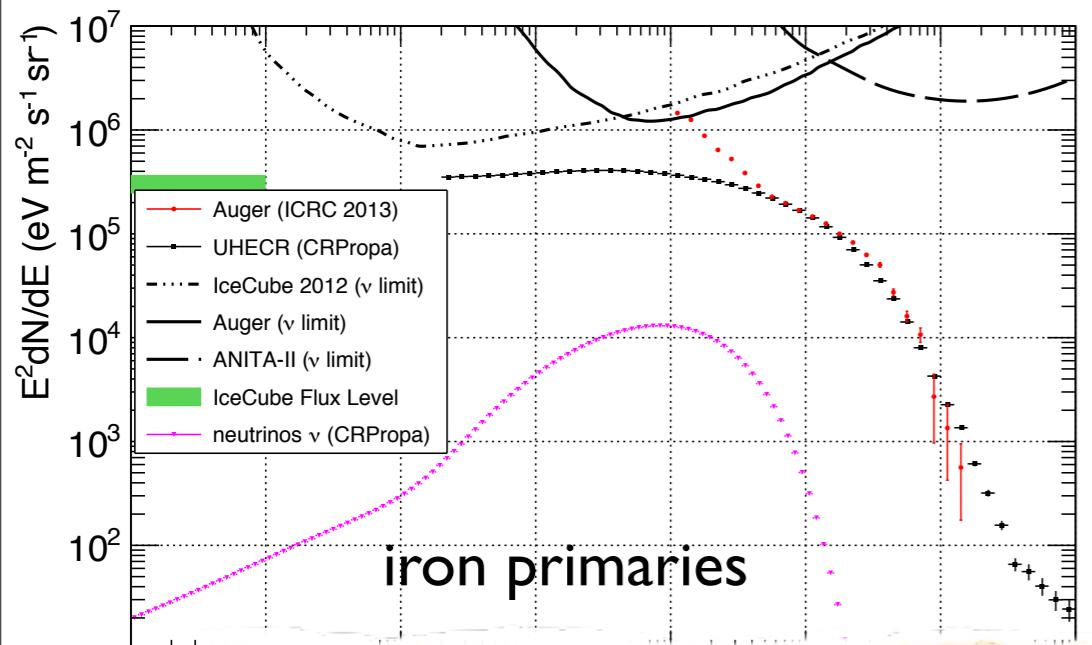

origin of high energy neutrinos

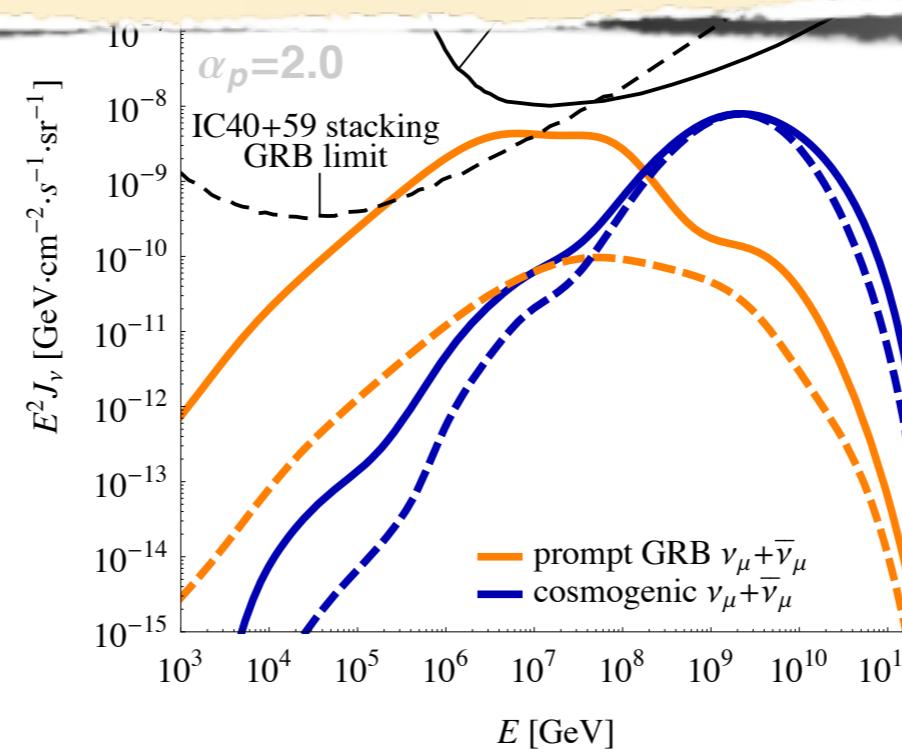

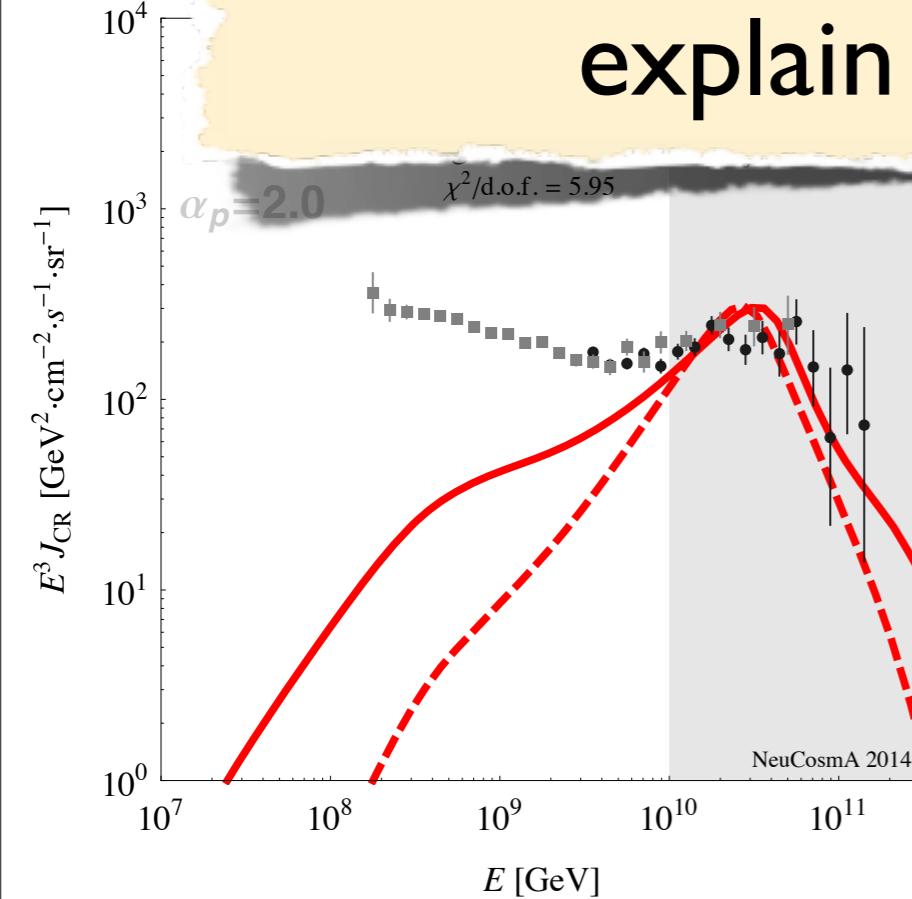

cosmogenic origin
[Sigl & van Vliet '14]

origin of high energy neutrinos

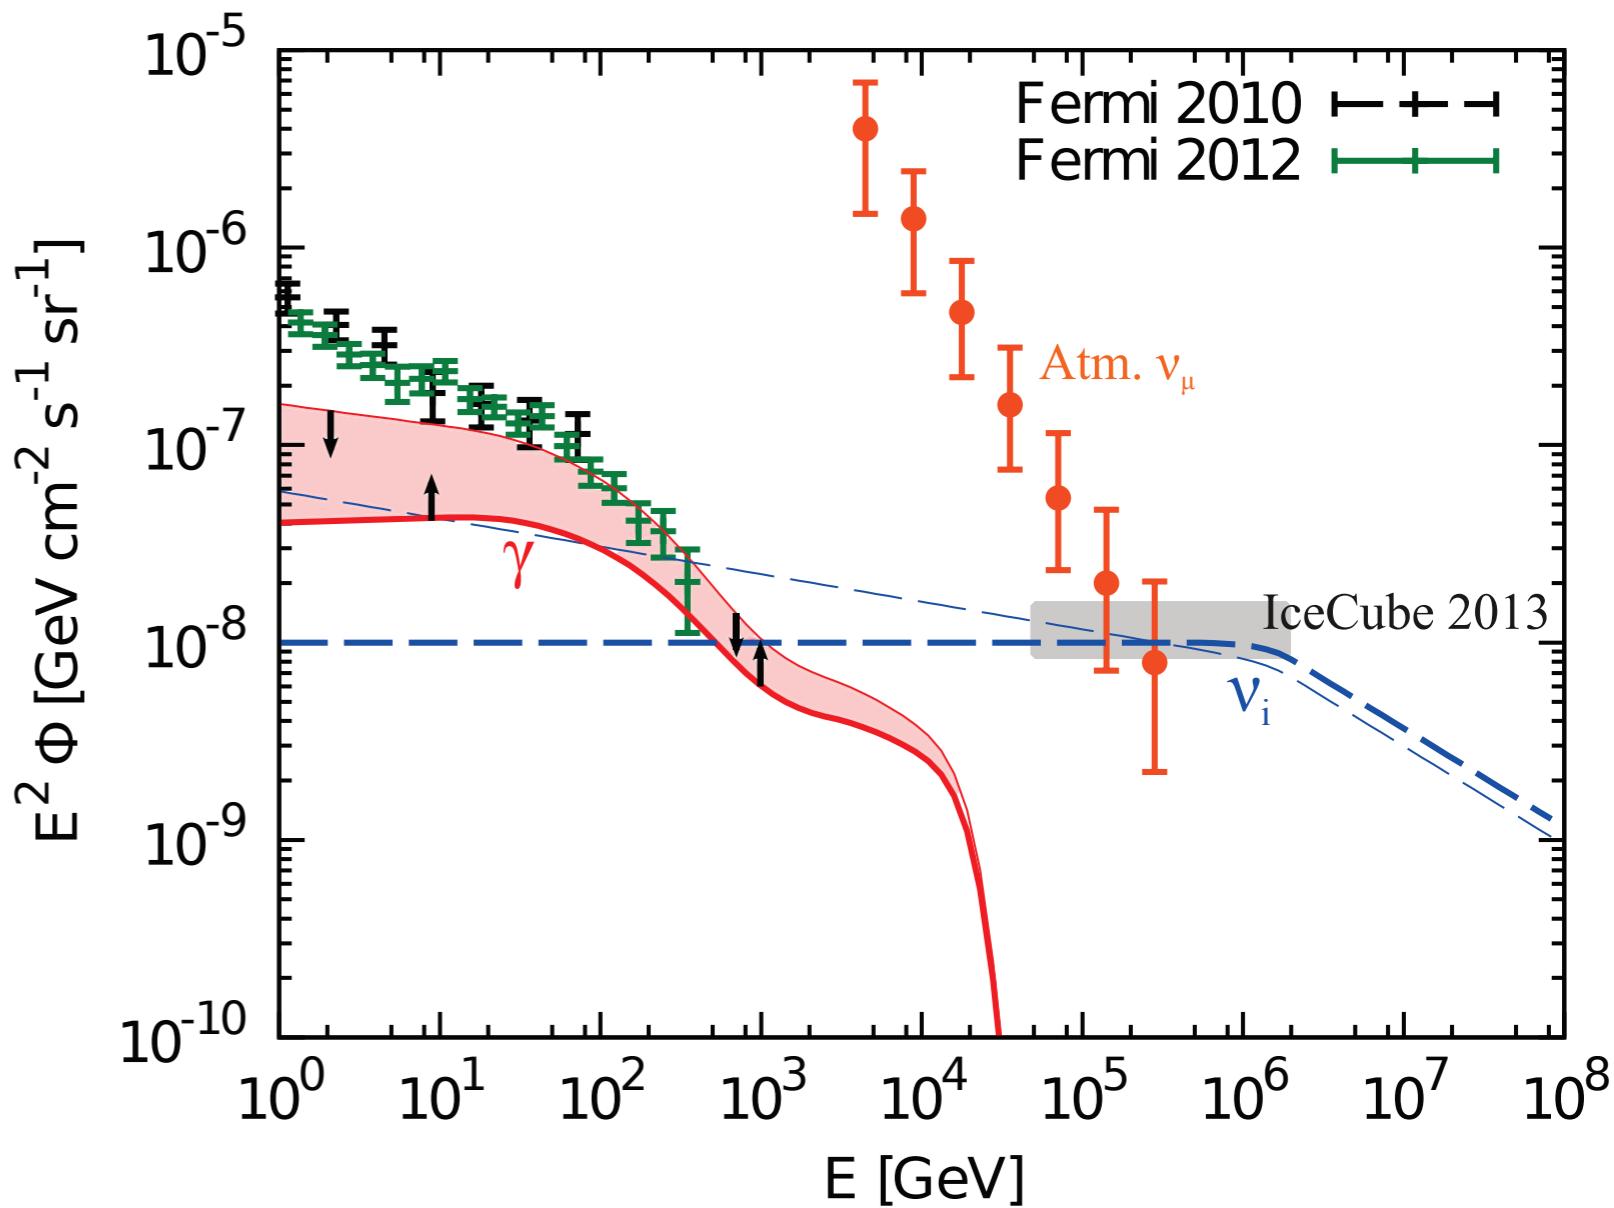

cosmogenic and GRB neutrinos cannot easily
explain IceCube PeV neutrinos

origin of high energy neutrinos

cosmic ray reservoirs

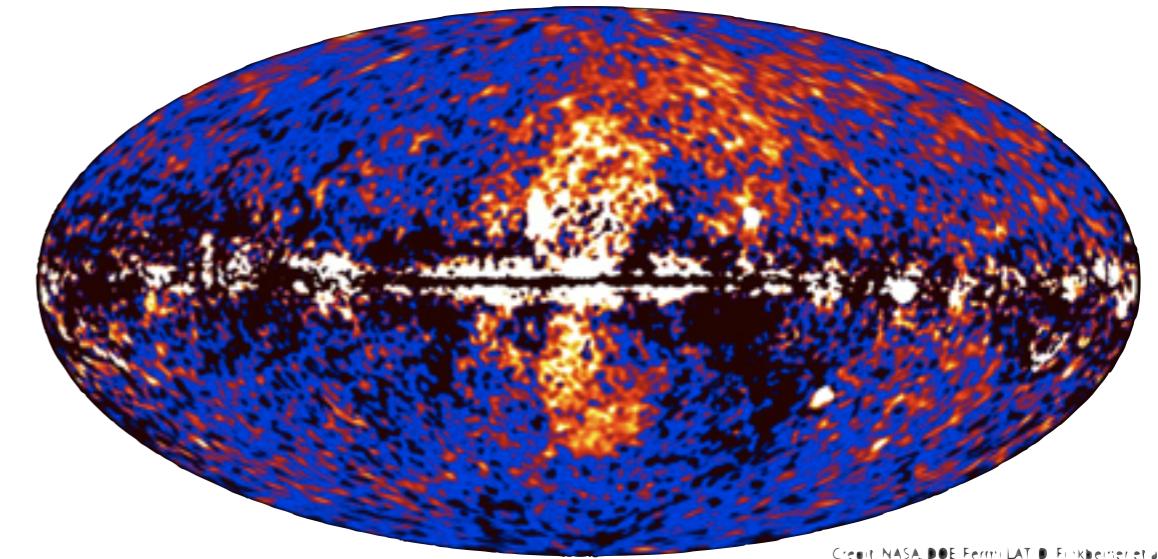

- ▶ cosmic ray reservoir (e.g.: starburst galaxies, clusters, etc)
- ▶ hadronuclear origin (pp scenario)
- ▶ escape of cosmic rays generate neutrinos
- ▶ explain simultaneously Fermi and IceCube data

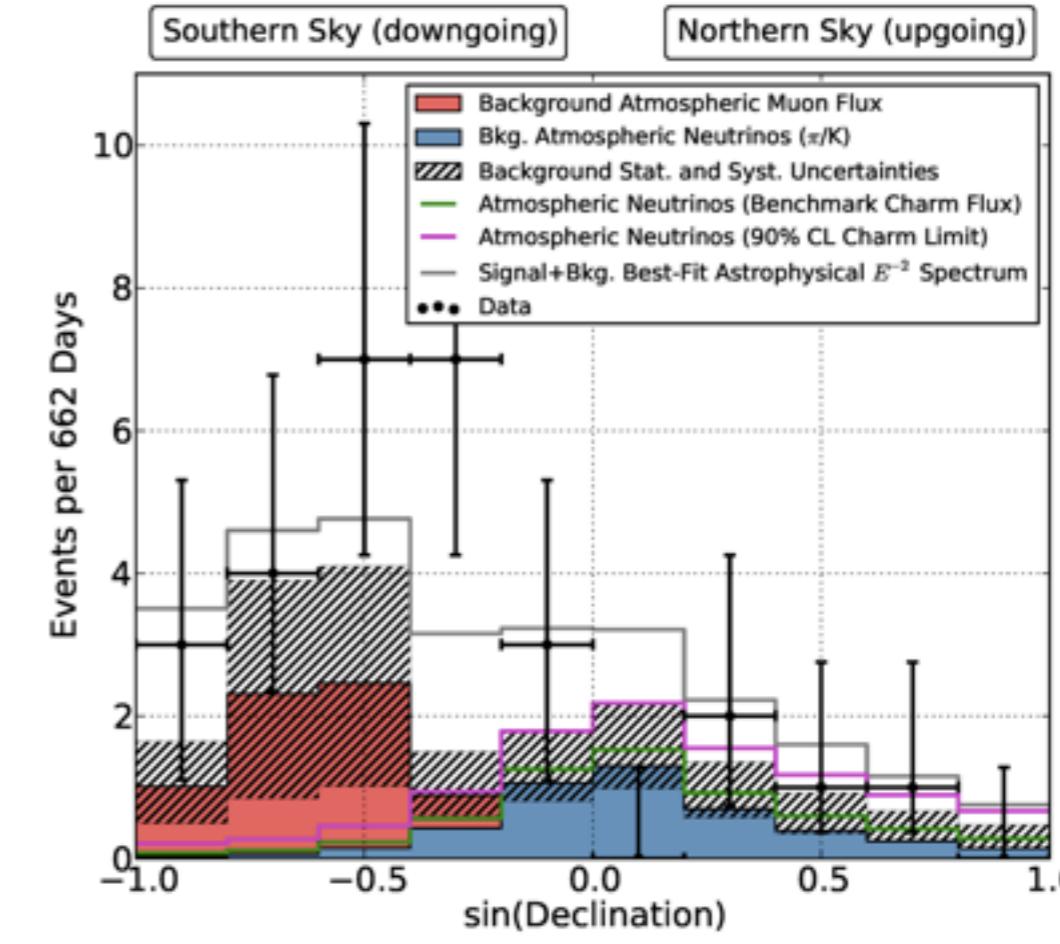

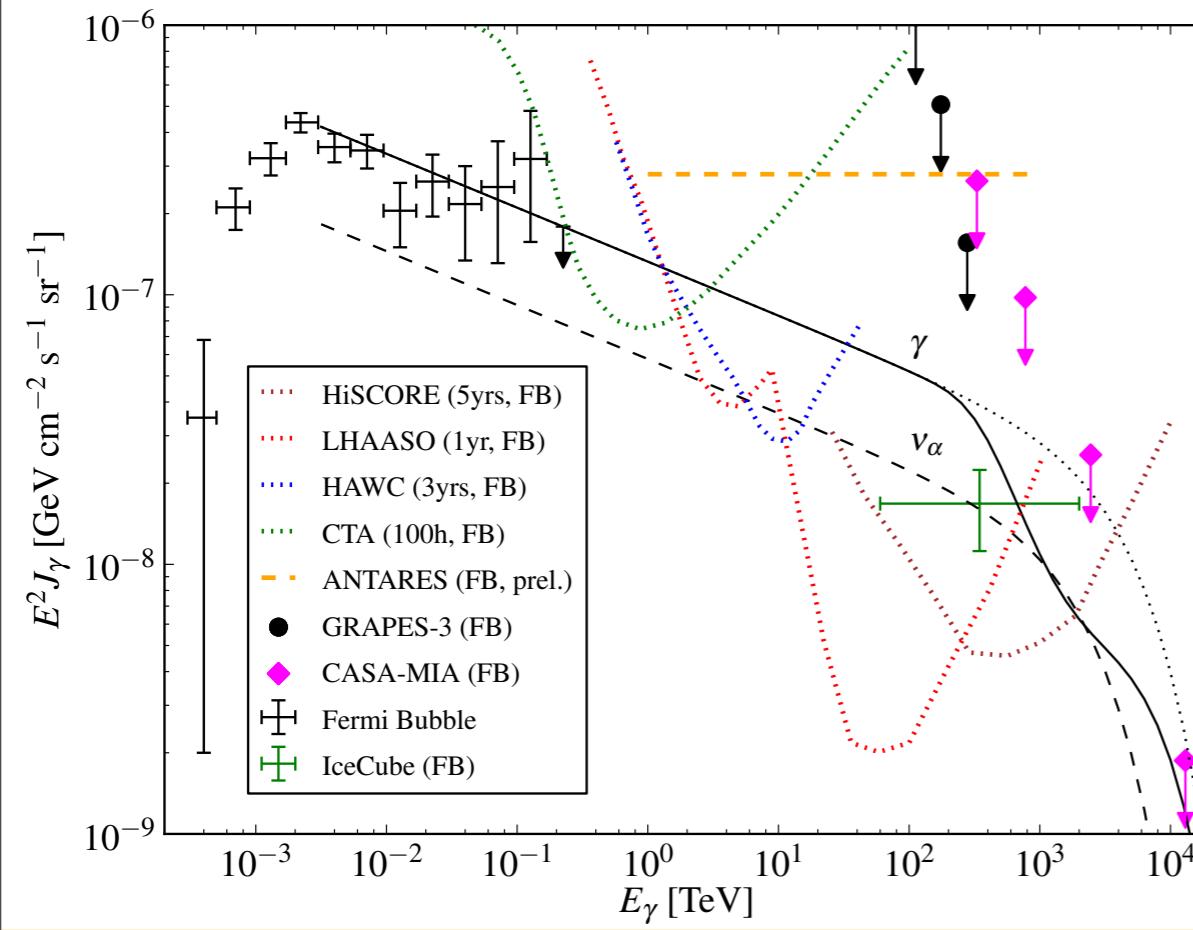

Murase et al. PRD
90 (2014) 023010

Fermi Bubbles and neutrinos

- ▶ Fermi bubbles origin still unknown → can produce associated neutrinos
- ▶ small extended excess in IceCube data → galactic center or Fermi bubbles? (not significant)

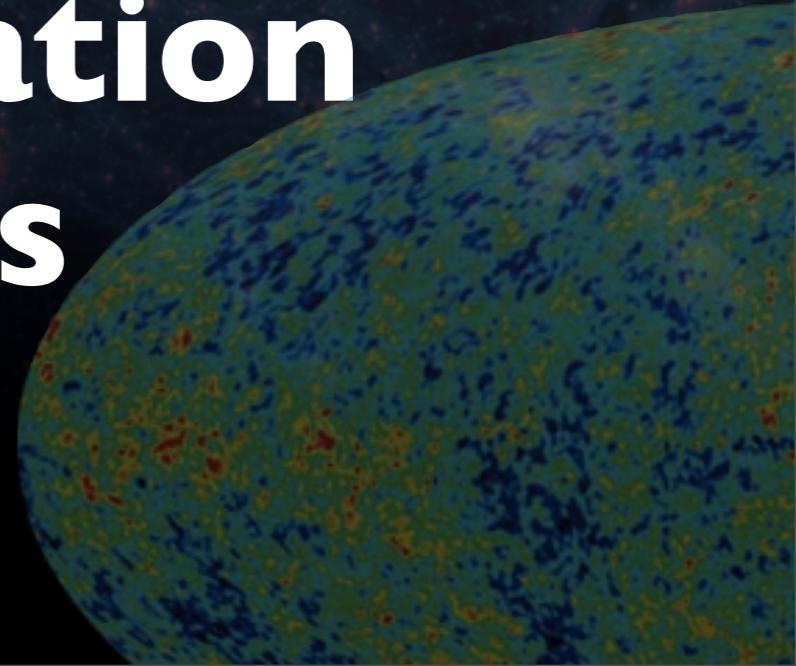

Ahlers & Murase, PRD 90 (2014) 023010

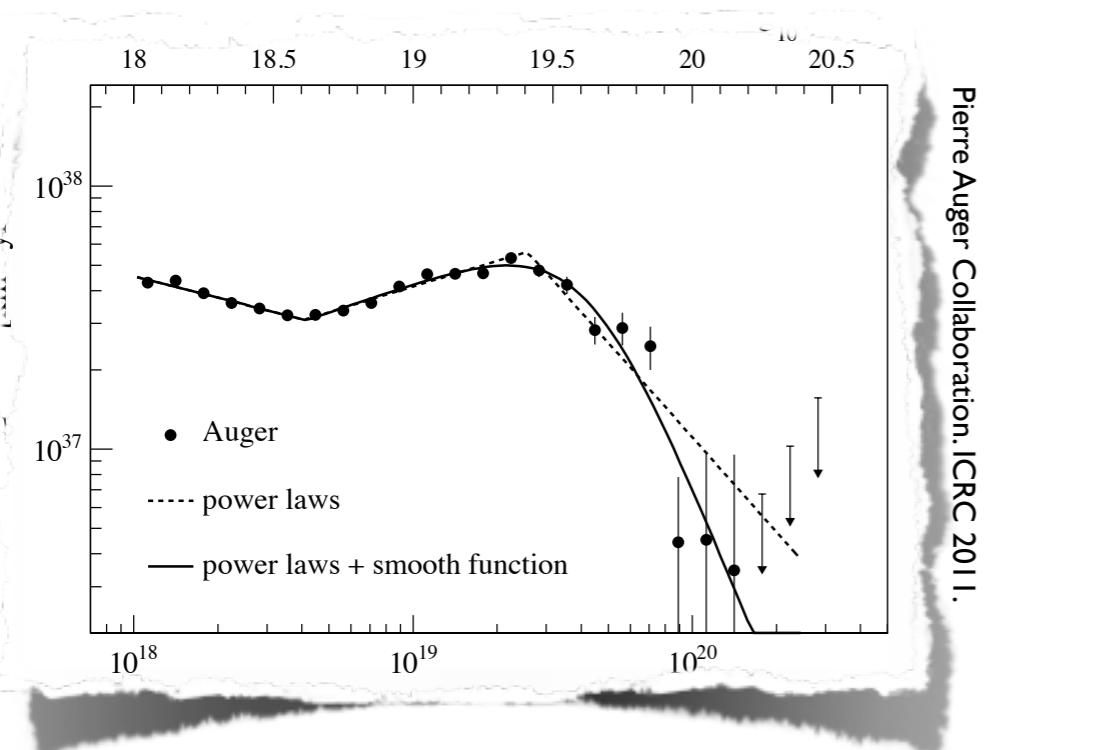

IceCube Collab. Science 342 (2013) 6161

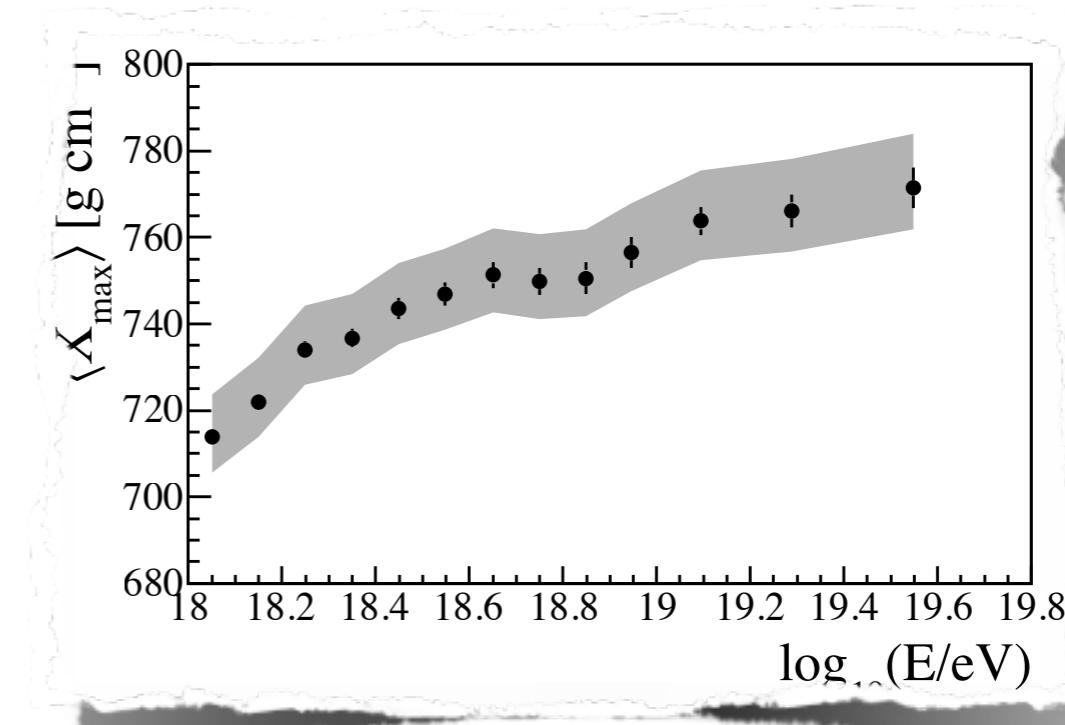

CRPropa: simulating the propagation of high energy particles

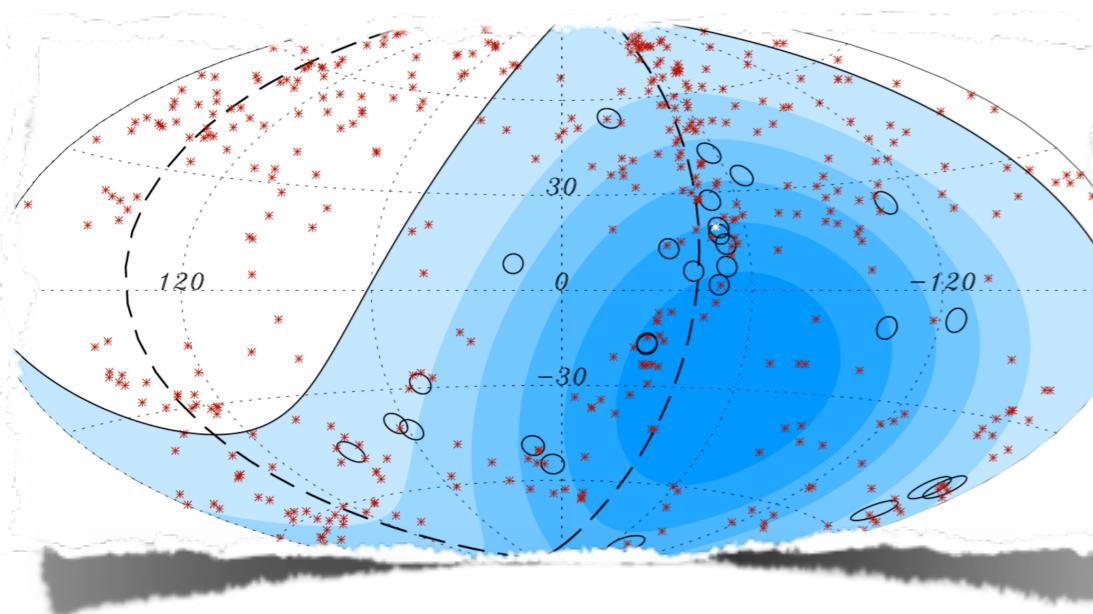

cosmic ray observables

Pierre Auger Collaboration, ICRC 2011.

Pierre Auger Collaboration, JCAP 02 (2013) 026.

Pierre Auger Collaboration, Science 318 (2007) 938.

- ▶ explain these three observables
- ▶ explain also gamma ray and neutrino counterparts
- ▶ magnetic fields and source distribution may affect spectrum and composition, and certainly affect anisotropy
- ▶ 3D simulations are needed
- ▶ large parameter space → fast simulations

CRPropa 2

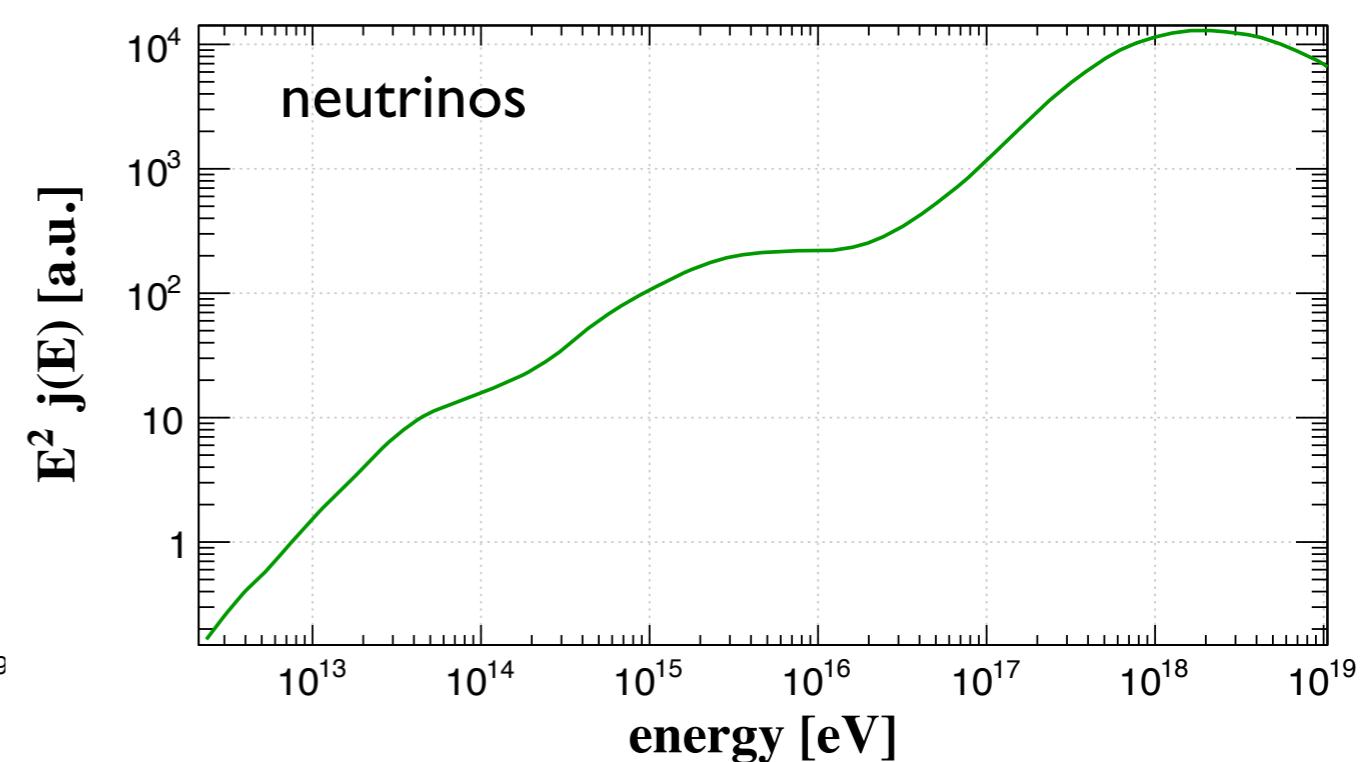

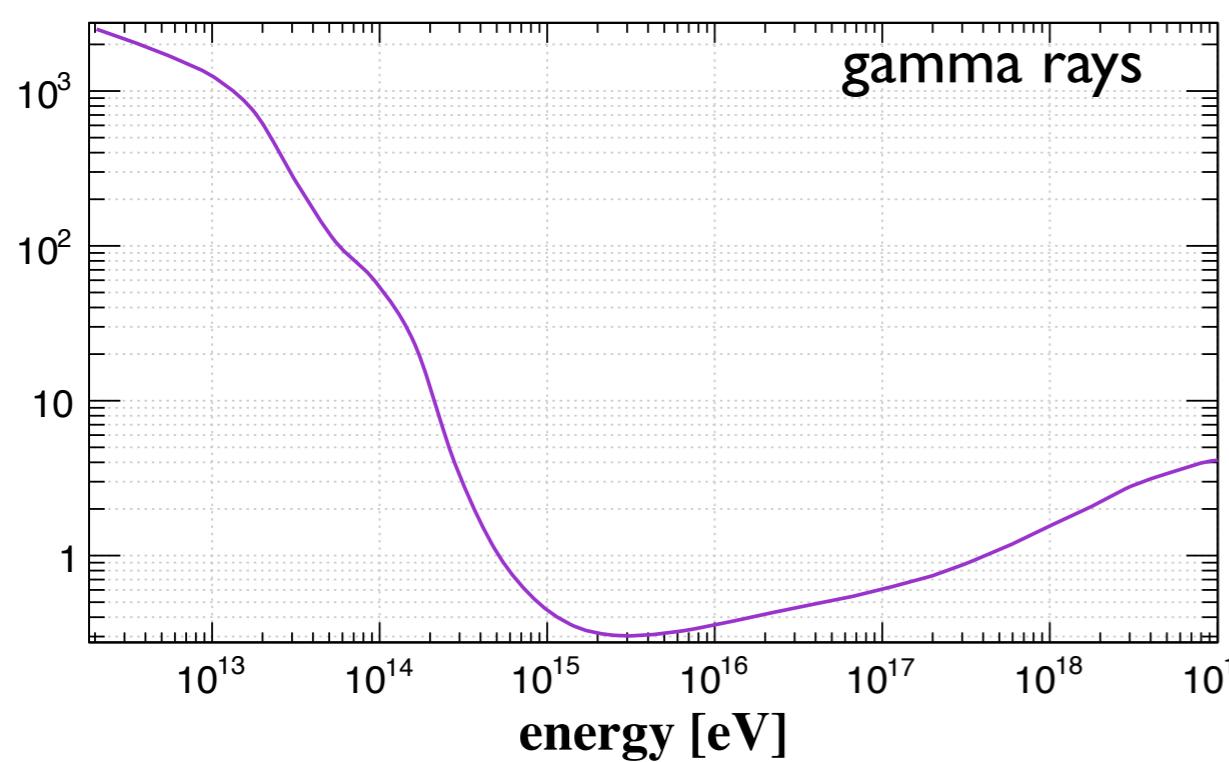

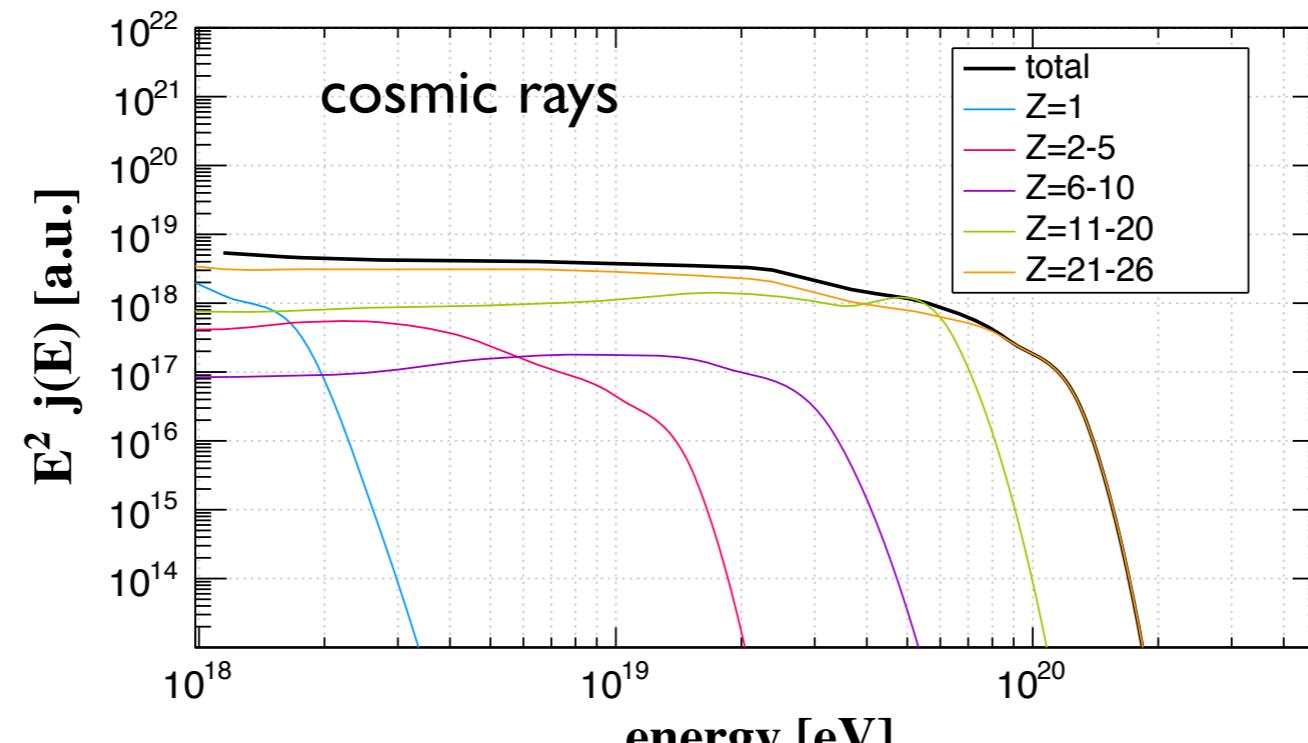

- ▶ “official” release
- ▶ see Kampert et al. *Astropart. Phys.* 42 (2013) 41
- ▶ 1D simulations with cosmology (e.g. source evolution, adiabatic losses, etc)
- ▶ 3D simulations in cosmic magnetic fields (uniform B, turbulent B, uniform grid)
- ▶ source (point sources, uniform distribution, density grid)
- ▶ interaction of particles with background photons (CMB, CIB, URB)
- ▶ secondary gamma rays (kinetic equations - DINT package)
- ▶ secondary neutrinos
- ▶ some improvements suggested by Kalashev & Kido [arXiv:1406.0735](https://arxiv.org/abs/1406.0735)

CRPropa 3

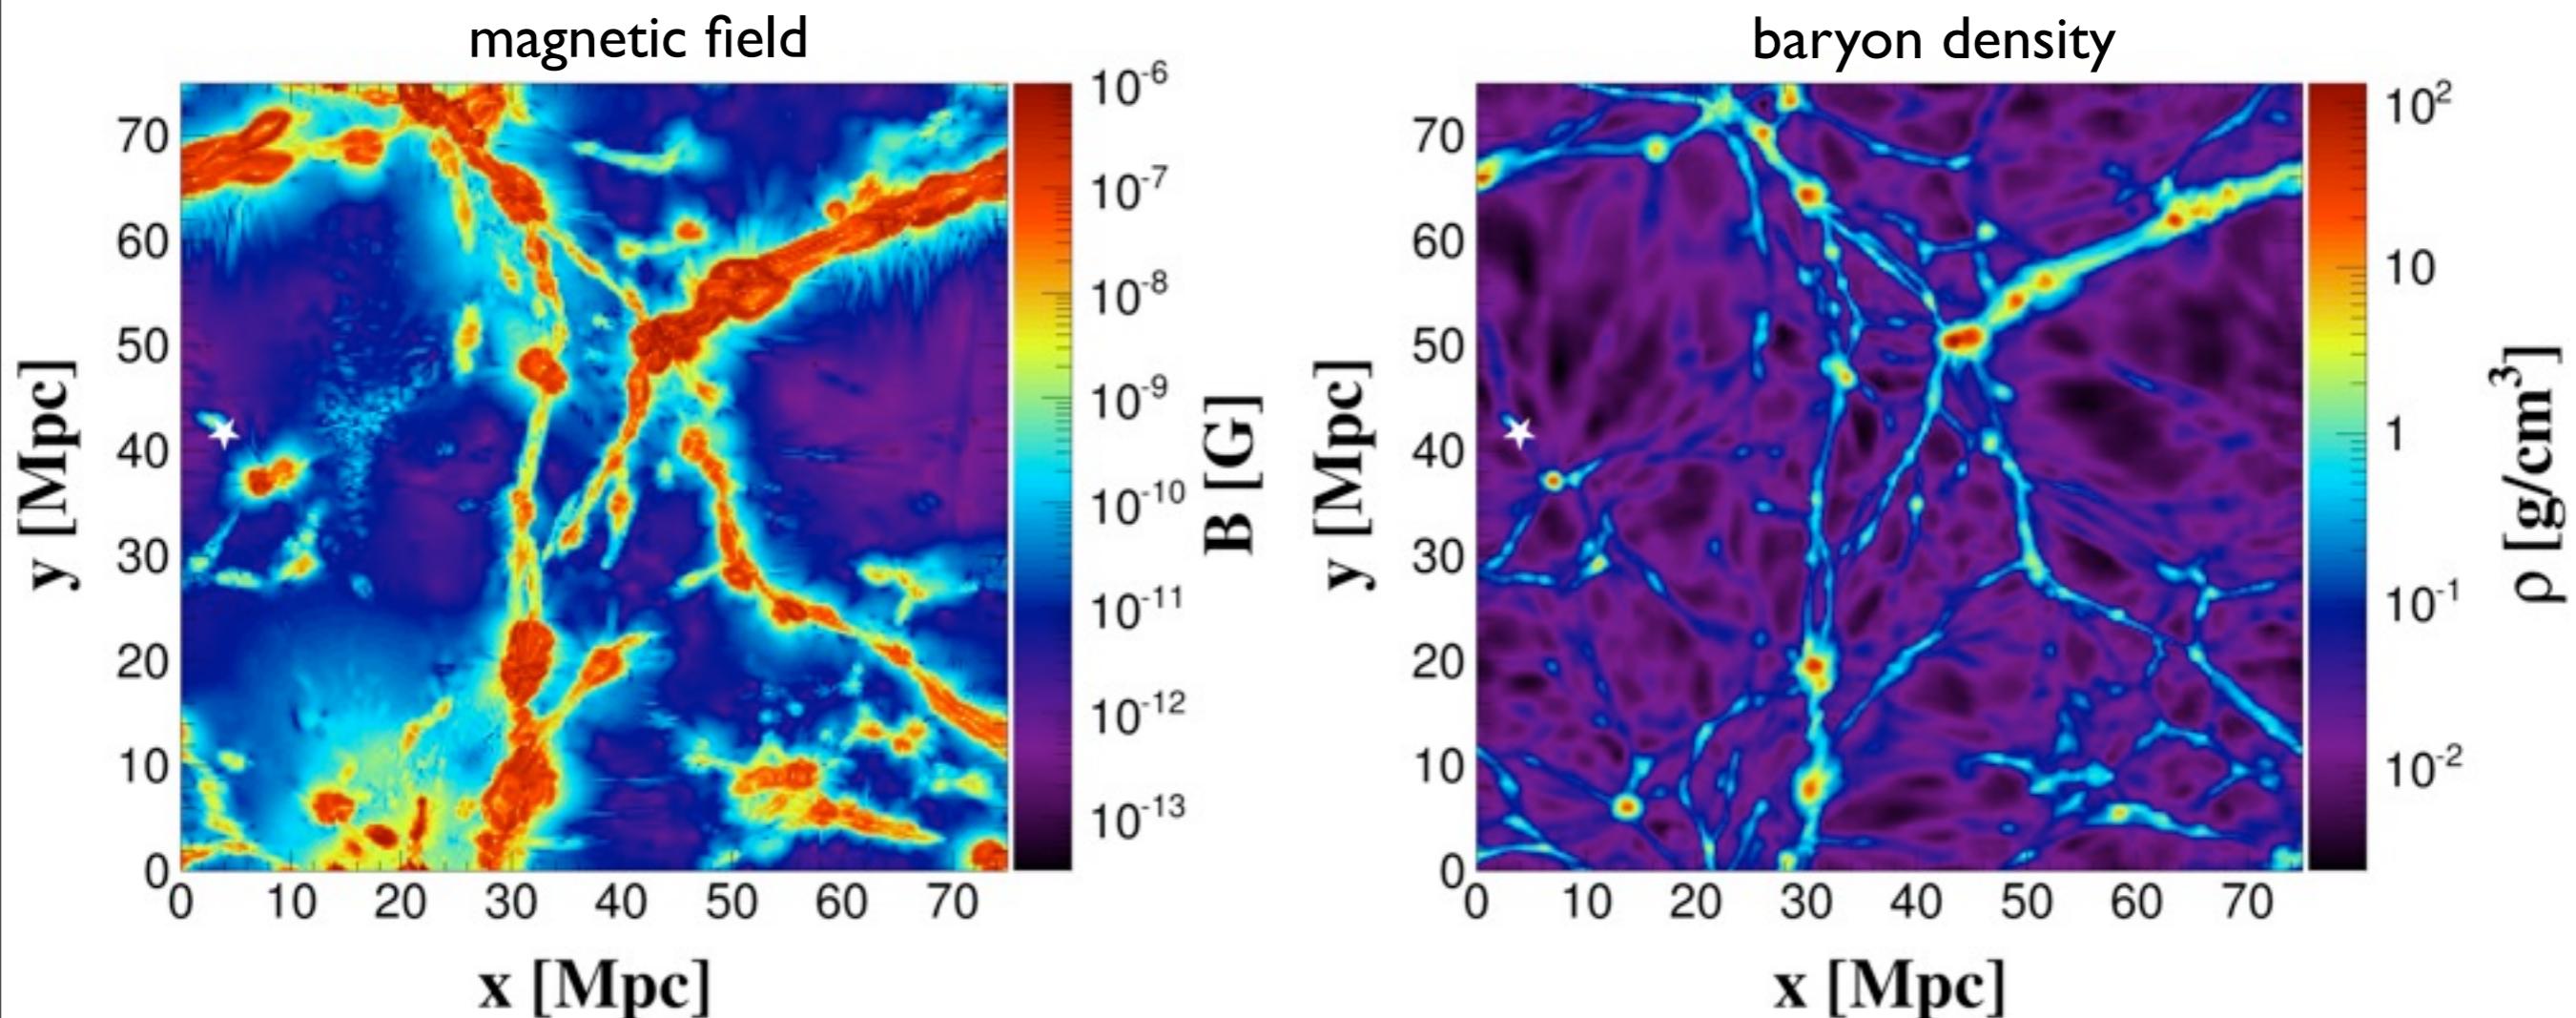

- ▶ development version
- ▶ see RAB et al. [arXiv:1307.2643](https://arxiv.org/abs/1307.2643)
- ▶ complete redesign of the code
- ▶ modular structure and python steering
- ▶ parallel processing
- ▶ 3D simulations with cosmology (“4D mode”)
- ▶ galactic magnetic field through lenses
- ▶ MC photon propagation (EleCa code)
- ▶ large scale magnetic fields through smooth particle formalism
- ▶ updated photodisintegration cross sections
- ▶ more IRB models
- ▶ improved interaction rate tables

<http://crpropa.desy.de>

ID example: UHECRs + secondaries

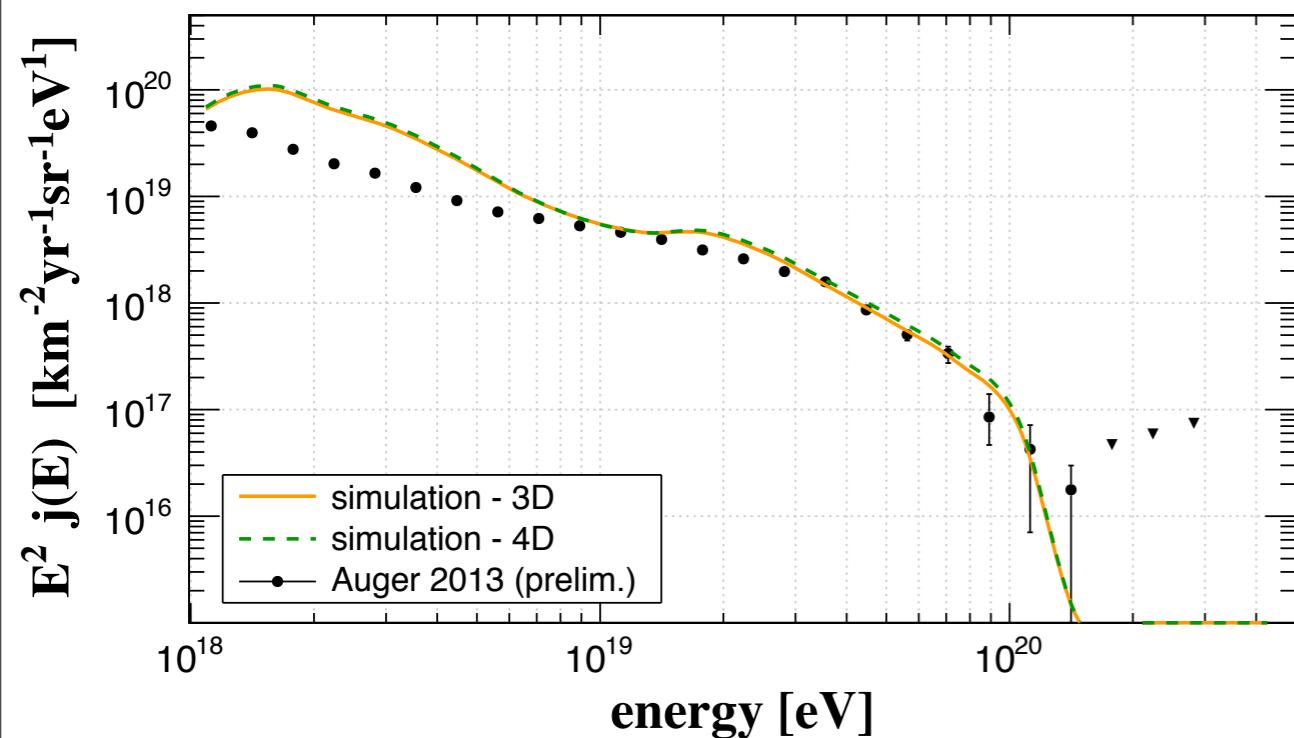

3D simulation setup: large scale structure

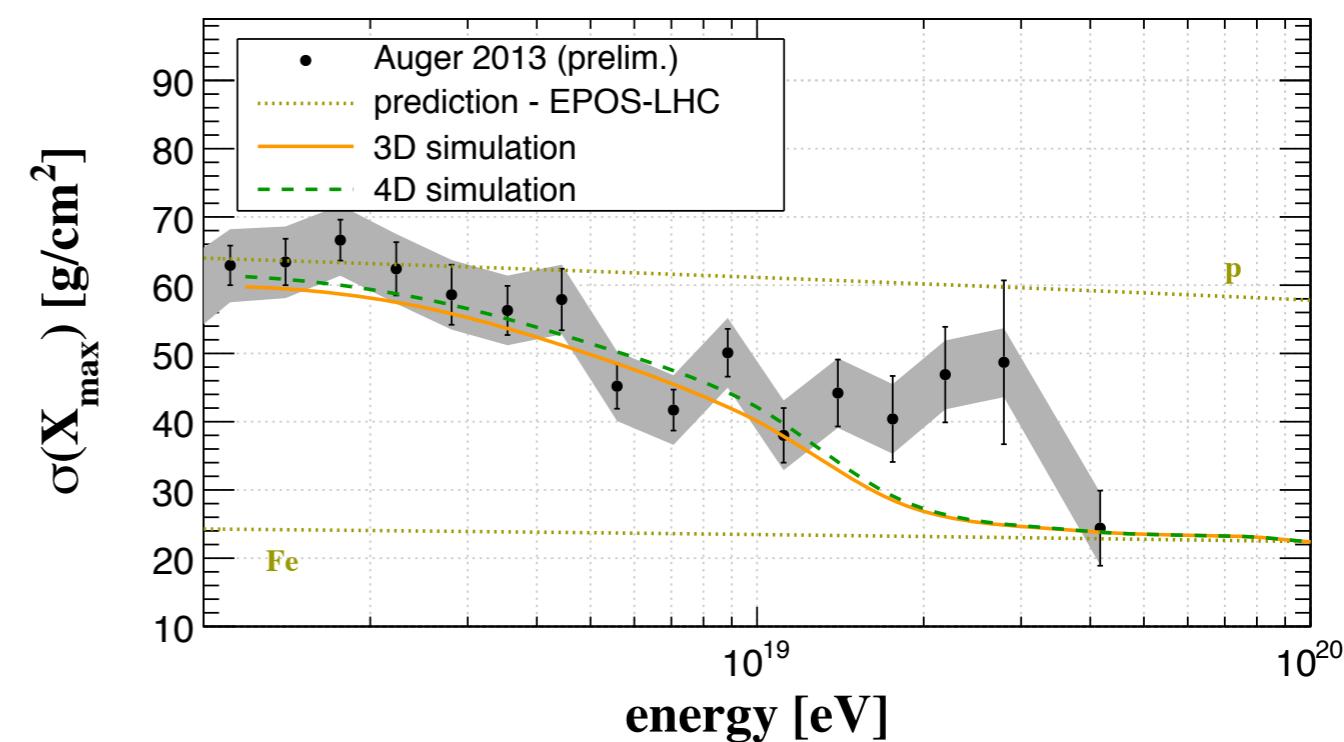

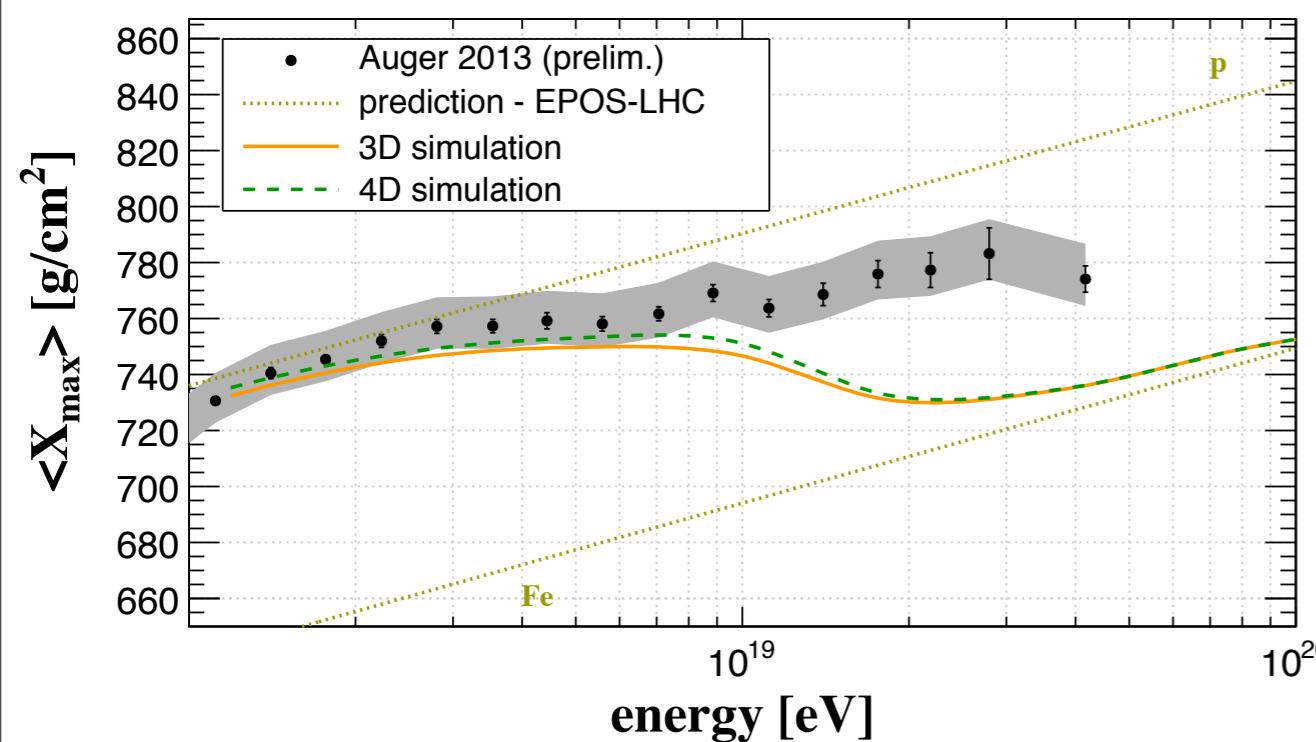

- ▶ MHD simulation: Miniati '02
- ▶ maximum rigidity = 1000 EeV
- ▶ maximum source distance = 4 Gpc
- ▶ sources following LSS baryon density

- ▶ magnetic field from the grid
- ▶ composition: 52% proton, 27% helium, 13% nitrogen, 8% iron
- ▶ minimum energy = 1 EeV

3D + 4D example: spectrum and composition

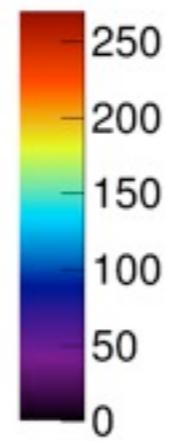

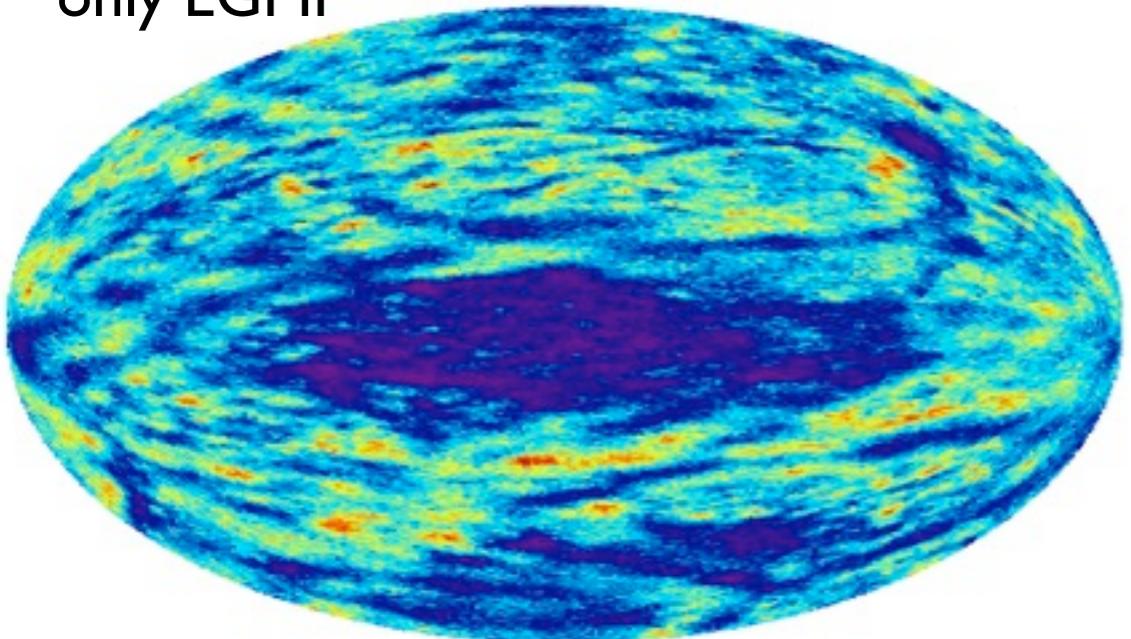

- ▶ adiabatic losses + source evolution + magnetic fields → realistic description
- ▶ 4D mode drawback: slow compared to 3D; particles are detected when its coordinates are within a hypervolume (3 spatial coordinates + time) around the observer

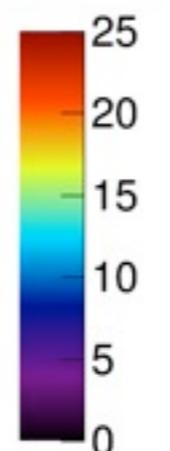

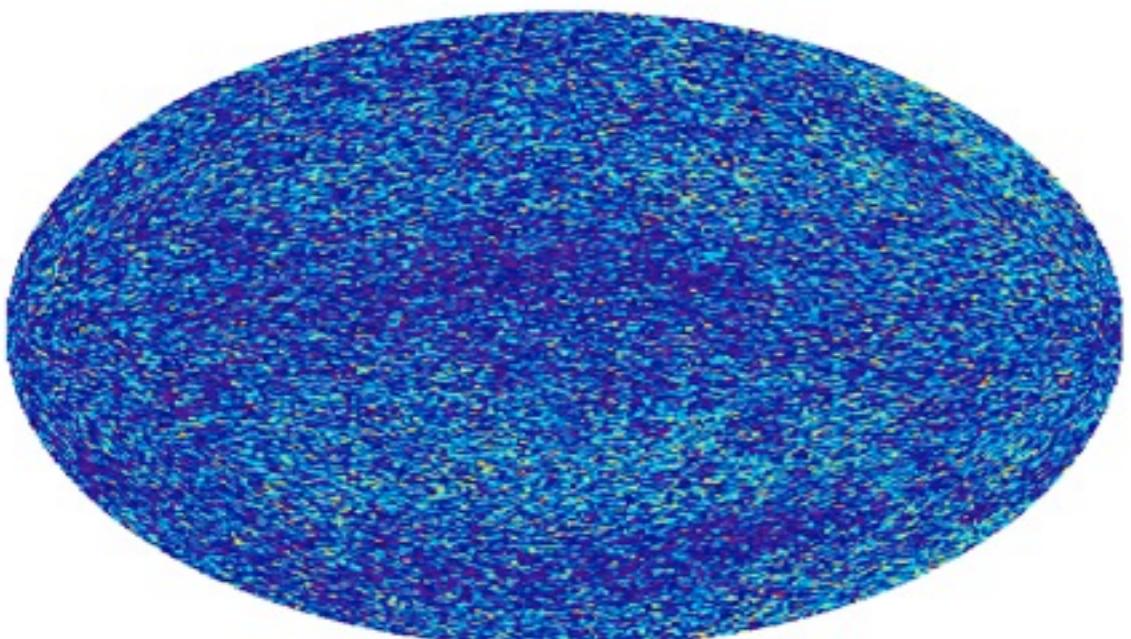

3D example: anisotropies

only EGMF

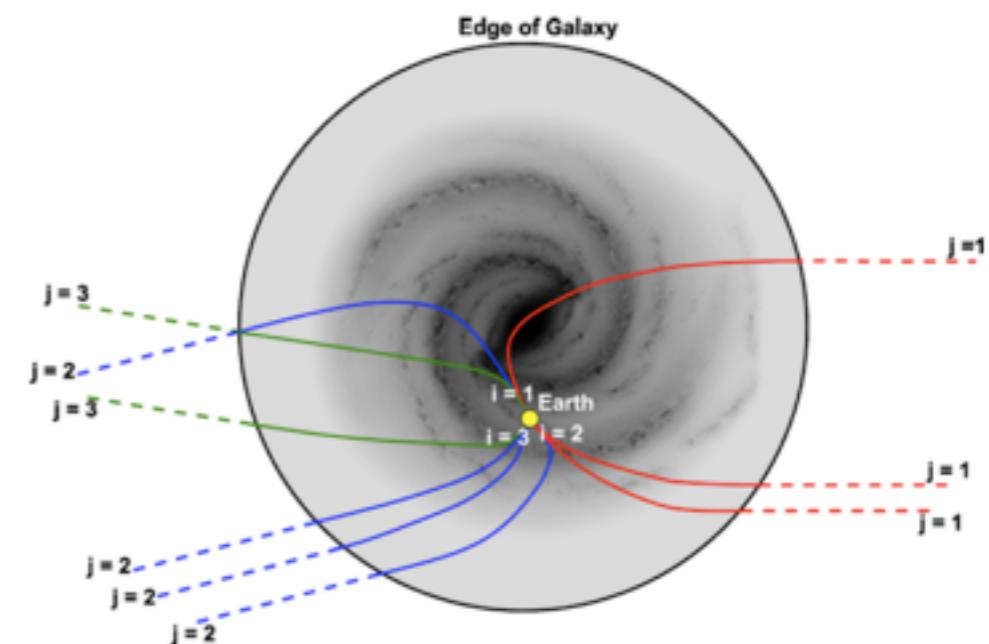

EGMF + GMF

galactic lensing

- ▶ assumes no energy losses
- ▶ each lens corresponds to a different energy bin
- ▶ lenses generated by backtracking protons to the galactic border
- ▶ nuclei have deflection Z times higher
- ▶ technique based on the PARSEC code [Bretz+ '14]
- ▶ lenses are applied a posteriori

summary and outlook

- ▶ difficult to construct model to explain main observables (spectrum, composition and anisotropies)
- ▶ understanding cosmic magnetic fields is crucial for particle astronomy
- ▶ status:
 - UHECRs can have mixed composition
 - highest energy cutoff may be due to maximum source acceleration
 - “local” sources may be needed
 - extra light component below the ankle
- ▶ cosmogenic neutrino and photon fluxes depend on cosmic rays composition, maximum acceleration and distribution of sources
- ▶ IceCube results represent the dawn of the era of neutrino astronomy
- ▶ multimessenger studies are now essential to explore all dimensions of the same problem
- ▶ future multimessenger studies: cosmic rays + gamma rays + neutrinos + gravitational waves

summary and outlook

- ▶ difficult to construct model to explain main observables (spectrum, composition and anisotropies)
- ▶ understanding cosmic magnetic fields is crucial for particle astronomy
- ▶ status:
 - UHECRs can have mixed composition
 - highest energy cutoff may be due to maximum source acceleration
 - “local” sources may be needed
